oxide, Cr_2O_3) spread in five layers. There are twenty-four such containers placed in two rows of six in two buildings. (Fig. 5.) At the outside of these rows are placed the corresponding heat exchanger, one double heat exchanger per catalyzing unit. In each section of the catalyzing building there are six Perrot furnaces B placed between the two rows of catalyzers. These furnaces use "Kraftgas" (a mixture of lean gas and coal gas) as fuel, and the hot gases are used for reheating as previously described. The additional supply of nitrogen needed (see p. 305) is brought to the catalyzed mixture through pipes β .

The process requires the addition of about 1,167 tons of water to the gas mixture per twenty-four hours.

The gases leaving the first catalyzing chamber analyze about 28 per cent CO_2 and 2.2 to 3.4 per cent CO; in the gases leaving the second catalyzing chamber the CO content is only from 1 to 1.6 per cent.

The temperature of the catalyzers does not exceed 500 deg. C.

The operation is controlled by:

Sixty thermocouples per catalyzer grouped in three series of twenty, each wired to a switchboard with a

FIG. 6. SCHEMATIC ARRANGEMENT FOR THE ELIMINATION OF CARBON DIOXIDE

single galvanometer. This galvanometer can be connected to any one of the thermocouples.

Three mercury manometers connected to Pitot tubes placed at the outlet of each catalyzing chamber and on the steam pipes.

Six electrically driven pumps for circulating the water, of which three 45-kw. are for tower 1 and three 40-kw. for tower 2. (Fig. 3.)

ELIMINATION OF CARBON DIOXIDE, COMPRESSION AND PURIFICATION

The catalyzed gas is collected in a gas holder, whence it is taken to be compressed. The compression takes place in five stages—namely to 5, 9, 27, 80 and 200 kg. When the gas is at 27 kg. pressure it is washed with water at the same pressure to remove the carbon dioxide. There are twelve compressors, of which six are of the Sulzer type and six of the Schwartzkopf type. Each one of them is driven by a two-cylinder-in-tandem gas motor 800 mm. internal diameter and 2-m. stroke. The total power required to drive the twelve pumps is 12,600 hp.

The gas, compressed to 27 kg., enters at j the absorption towers A (Fig. 6), which are provided with Raschig rings. The dimensions of these towers are 1.2 m. diameter x 12 m. high. Six centrifugal pumps D of the Sulzer type driven by 180-kw. motors circulate the necessary water, which enters the top of the towers

A at *i*. The gas, which leaves the towers at *m*, is led to purifiers *E* and through the pipings *n* back to the compressors. The wash water is sent through pipings *K* to a Pelton turbine *B* direct-connected to the electric motor *C*. The expansion of the compressed water takes place in this turbine and 60 per cent of the original energy required to compress it is thus recuperated. From this turbine the water falls into a reservoir where the CO_2 is separated and sent to a gas holder through pipings *b* and the water thus freed returned through pipings *l* to the water compressors.

There are twelve absorption towers and twelve separators, divided into six groups, each group having its own pump.

The operation is controlled by:

A velocity indicator for the inlet gases.

An indicator giving the volume of the gas taken from the gas holder.

Indicators showing the presence of carbon monoxide in the atmosphere of the building.

About 3,200 cu.m. of water is required per hour. The energy spent to compress the water is about 0.4 hp. per cu.m., when the amount of energy recuperated in the Pelton turbine is taken into consideration.

At the outlet from the towers the CO_2 content of the gas is not more than 0.8 per cent.

ELIMINATION OF CARBON MONOXIDE

A series of tests were made to eliminate the carbon monoxide by the use of an appropriate absorber. After many trials with various absorbers the Badische Anilin- und Soda-Fabrik has adopted an ammoniacal solution of copper formate for the absorption of CO .

The gas, compressed to 200 kg., enters the absorption

FIG. 7. SCHEMATIC ARRANGEMENT OF INSTALLATIONS FOR THE ELIMINATION OF RESIDUAL CARBON MONOXIDE

towers A (Fig. 7) at the bottom at *a*. There are fifteen towers working in parallel. They are provided with Raschig rings. The ammoniacal solution, compressed to 200 kg. by twelve piston pumps *P* driven by steam engines *M*, is sent to the towers A through *b*. The gas leaves the towers at *c*, enters the separators *B*, where the liquid in suspension is separated, and then to towers with soda lye, where the remainder of CO_2 is removed. The circulation of the soda lye at a pressure of 200 kg. is made by two pumps analogous to pumps *P*.

After expansion the cuprous solution is sent to a regenerating plant, where it is submitted to the action of heat and vacuum.

The hourly consumption of ammoniacal solution is about 40 cu.m., which can absorb about 720 cu.m. of carbon monoxide. The daily consumption of formate is about 320 kg. The hourly consumption of soda lye is about 8 cu.m.

The twelve circulating pumps are on the ground floor

of a 75 x 20-m. building. The towers and the separators are located along one of the long sides of the building. The towers are forged steel tubes 12 m. long, 80 cm. outside diameter and 12 cm. thick. Each tower is provided with a level indicator showing when it should be disconnected for the removal of the lye.

(Part II will be published in a subsequent issue.)

Gutta Gaekwar, a New Base for Chewing Gum

BY FREDERIC DANNERETH, PH.D.

Some time ago our attention was called to a new material which, it would seem, will become of considerable importance in developing products in the industry of plastics. The material is known commercially as gutta gaekwar, and we are advised that it is the coagulated milk juice of latex-bearing trees in Borneo. The product has been refined to a certain extent, so that it appears with the consistency of hard cheese, and it can be cut in slices with a knife. The gutta has a cream white color, but so far as our examination has gone it appears to be a straight natural product, not mixed with other guttas or milk juices.

It is almost tasteless when chewed, has a slightly sweet odor and has about 15 lb. of water in 100 lb. of the material as imported. The resin content of the actual gutta, after the water has been removed, averages 65 to 66 per cent. These resins have a melting point of about 160 deg. C. They have many peculiar and interesting physical properties, of which one is of particular importance—they contain more than 50 per cent unsaponifiable matter, and the unsaponifiables bear a close resemblance to the unsaponifiable matter found in wool grease.

When the original gutta is heated in the oven to a temperature of 100 deg. C. it becomes very tacky, and it is easy to draw "strings" when stirring the mass. From this we conclude that the material will be of interest in cases where a strong "binder" is needed for plastic masses. The material sent to this laboratory was in the form of a brick weighing about 5 lb., but after resting in the dry air of the storage room for a few weeks it lost a large part of its water. The dry material has, however, not lost any of its valuable properties. It may be rendered plastic by heating in a double-jacketed kettle or in an oven. In this condition it may be mixed with powdered minerals such as whiting or iron oxide, or it may be mixed with powdered sugar or powdered starch. Thus it has been possible to produce compact masses which can be formed into a variety of shapes.

The special uses for which gutta gaekwar seems adapted are:

1. As a binder in place of shellac, in preparing plastic masses.
2. As a base for chewing gums (to be mixed with softeners and sugar).
3. As a substitute for chicle (by adding waxes to the gutta).
4. As an organic compounding material in rubber mixes (used for impregnating cotton duck in the manufacture of rubber belting, rubber hose, and rubber packing).
5. As a compounding material in rubber compounds (used in the manufacture of double texture raincloths).

Although this new gutta is not of domestic origin, we feel that its interesting properties may prove of value to some of our colleagues in the organic chemical industries.

High-Frequency Induction Steel-Furnace

A Practical Combination of Crucible-Melting Flexibility With the Advanced Practice of Electric Melting
—A Means for Producing Alloys Whose Proportions Are Accurately Reproducible—
Virtually an Electric Crucible

BY E. F. NORTHRUP

THE furnace which we here describe is one of several specific commercial applications of Ajax-Northrup High-Frequency Induction Furnaces which the Ajax Electrothermic Corporation has developed.

This specific form of furnace, which for brevity we designate as a "10-In. Conical Pouring Furnace," is designed for operation with high-frequency current supplied by a standardized high-frequency converter set of 20-kw. capacity. All furnaces which operate with high-frequency current require a frequency of from 10,000 to 25,000 cycles per second.

The high-frequency converter set is a piece of static apparatus which performs the function of converting commercial current of ordinary frequency, usually sixty cycles, into current of the high frequency required. A 20-kw. high-frequency set occupies a floor space of 31 in. front by 41 in. deep and stands 67 in. high. The set is illustrated in Fig. 1.

THE HIGH-FREQUENCY CONVERTER SET

It will be seen from the illustration that the set consists of a metallic cage faced with a switchboard. On the switchboard are mounted a control wheel for varying the power, a main line switch, an indicating wattmeter, and an alcohol dropper. This cage contains all of the parts required for a 20-kw. high-frequency converter. There are but three essential parts of the apparatus, all contained in the cage. These are: Twelve General Electric Co. condensers; a transformer of special design, made by the American Transformer Co., with internal reactances; and a discharge gap. This latter has two electrodes which are raised and lowered vertically over a surface of mercury contained in a metal container. The raising and lowering of these electrodes are effected by means of a hand-wheel on the face of the switchboard, the connection to the electrodes being made through the medium of a flexible shaft. The power delivered by the high-frequency converter set may be varied from zero to maximum by changing the distance of the electrodes above the surface of the mercury. All low-frequency, high-tension circuits are housed in the metal cage, which is itself connected to earth.

The transformer steps the line voltage up to 6,600 volts, but no danger of contact with this high voltage is possible because the high-tension parts are housed in the grounded metal cage. The high-frequency converter set, of standard construction, operates on single phase or one leg of a polyphase circuit of 220 volts and sixty cycles. When used with the furnace about to be described this set delivers current to the furnace at a frequency of approximately 15,000 cycles per second.

The set is designed for continuous operation and

will have a long life, as there are no parts which are moving nor are there any parts which suffer rapid depreciation. The power which is drawn from the supply line is at all times shown by the indicating wattmeter on the face of the switchboard, and this power may be varied by the control wheel in infinitesimal steps from zero to a maximum of 20 kw. No power is wasted in rheostats or other like devices. The current taken by the set is not far different when operating with small power than when operating with large power, and consequently as the set draws more power from the line the power factor improves, reaching at full power over 70 per cent.

THE FURNACE

The furnace which it is the purpose of this article to describe and which is operated with current obtained from the above-described high-frequency converter set, has the following construction:

A strongly built box is made of asbestos board and is approximately cubical in form, being 16 x 16 x 14½

FIG. 1. VIEW OF A 20-KW. HIGH-FREQUENCY SET

in. This box contains the inductor coil, the electrical insulation, the small amount of heat-insulating material required and the crucible in which is placed the metal to be melted. For brevity we shall speak of this as "the furnace."

The furnace is placed on a table made of heavv

asbestos board. This is 20 x 36 in. and stands 15 in. high. The leads from the high-frequency converter set are permanently connected to metal pieces beneath the cover of this table. When the furnace is placed upon the table, contact is made with these metal pieces by two metal feet at the base of the furnace box. The furnace is so designed that when a melt is completed the furnace may be lifted off the table by two men using suitably designed handles and may then be tilted and the contents poured. The handling of the furnace and the pouring are done in the usual manner in which one handles and pours metal from a crucible which is lifted and rotated by a so-called "bale."

CONSTRUCTION OF THE FURNACE

The construction of the furnace proper is exceedingly simple and consists of only two essential parts—the inductor coil and a crucible. The latter fits within the inductor coil, with a suitable small amount of electrical and heat insulation between the two. The inductor coil is conical in form, the large diameter of the cone being uppermost. The diameter of the base of the cone

FIG. 2. CROSS-SECTION OF STEEL FURNACE

is $4\frac{1}{2}$ in., the top of the cone is $10\frac{1}{2}$ in., and its vertical height is $10\frac{1}{2}$ in. The inductor coil itself consists of thirty-seven turns of $\frac{3}{8}$ -in. copper tubing flattened and wound edgewise. Arrangement is made for circulating a small stream of water through this copper coil both to maintain it cool and to keep its resistance low. The inside of this inductor coil is lined with a cylinder of micanite (a kind of micanite having no organic binder) about $\frac{1}{4}$ in. thick. This gives both electrical and heat insulation.

The crucible has the same conical shape as the coil and is within it. A space of about $\frac{1}{2}$ in. between the outside of the conical crucible and the inside of the micanite cone is filled with a suitable powdered heat insulator, lampblack being a very suitable material for a steel-melting furnace, although electrically sintered and powdered magnesia or several other materials may be substituted for lampblack where strictly carbon-free melts are demanded. The construction is shown by the cross-sectional view in Fig. 2.

When a crucible has become used up, it is easily withdrawn from the powdered encasement of heat-insulating material and a new crucible inserted in its place. This conical crucible is designed to hold from

50 to 60 lb. of metal of the density of steel, and will melt and pour this weight of any metal of high specific resistance like a ferrous alloy which melts under 1,200 deg. C. Where metals are to be melted which require excessive temperatures, like a very low-carbon steel, it is not desirable to attempt to melt and pour at one time more than 25 lb., though it is possible to pour somewhat larger amounts. In the case of the alloy used in casting the metal parts of typewriters 50-lb. pours have been made with much success.

FEATURES OF THE FURNACE

Any of the metals or alloys which are to be melted can be placed in the crucible in the form of turnings or in the form of masses which may have a subdivision down to the size of a pea, but not in the form of a fine powder. The heating of these metals when above the temperature at which iron loses its magnetism is due entirely to the large currents which are induced in the mass of the metal. When the metal is magnetic, there is further development of heat due to the hysteresis losses caused by the rapid reversals of the magnetism. Iron and steel, therefore, are heated with particular facility because of this fact and likewise on account of the high specific resistance of these metals.

A feature of marked value when melting alloys is the rapid stirring which takes place in the molten metal. This stirring is not a circular motion, but an upward motion in the axis of the pool and a downward motion in the circumferential region. When the power is on, the surface of the metal is not level, but considerably crowned. This stirring action is due solely to the action of electromagnetic forces and is in no sense a heat phenomenon. Its effect in insuring a thorough mix of the components of an alloy is very beneficial. In melting steel all dross of the metal is swept upward to the surface, where it remains. It is possible to pour castings which are very clean and with the constituents of an alloy very homogeneously distributed. For example, the Western Electric Co. has been pouring with a furnace of this general type an alloy of pure electrolytic iron and pure electrolytic nickel. The metal was cast in bars about 20 in. long and $\frac{3}{4}$ in. in diameter. Repeated analyses show that the composition of these bars varied less than 0.01 per cent for portions of the metal selected from different parts of the bar. This homogeneity attainable in an alloy was found to have great value in the case of alloys used for drawing into thermocouple wires.

HOW A POUR IS MADE

When a pool of 20 to 50 lb. of molten metal has formed in the crucible a pour is made as follows: The two handles shown in the illustration, Fig. 3, are attached to opposite side walls of the furnace. The furnace is lifted from its table by two handlers, one of whom rotates the furnace by means of the double handle and makes the pour. It is not difficult to guide the molten metal into a small orifice.

In Table I is given a typical melt made with one of these furnaces. The material to be melted was 20 lb. of steel turnings. These had evidently been gathered off the floor. They contained much admixture of dirt and oil and formed a bulky mass. At the beginning of the melt the entire furnace, including the crucible, was at room temperature. The crucible was filled to the top with steel turnings. This took about one-quarter of the 20 lb. A record of the progress of the melt taken

directly from the note book as there recorded is given in Table I.

Commenting on this melt, it may be stated that we could have continued to add turnings until 50 lb. of

1:28	18	Put one handful of flux on surface of molten metal.
1:31	20	Melt complete and quite fluid.
1:37	20.5	Poured melt which when cold weighed 16 $\frac{1}{2}$ lb.

*Test by E. F. Northrup and Bert Robbins, Nov. 20, 1920.

the material became melted; but this was not done, as no more material was at hand.

At another time, using the same furnace and crucible, 50 lb. of the metal out of which the castings for type-writer frames are made was melted, with an average

FIG. 3. MAKING A POUR

input of 17 kw., in two hours and twenty-six minutes, and five minutes later poured into molds. The metal was very fluid and fine castings were obtained. The metal is non-magnetic, and the melting was produced solely by the eddy currents induced in the irregular masses of metal placed in the non-conducting crucible. For efficient and rapid melting of a metal of this character a molded carbon or graphite crucible should be used.

SUMMARY OF UNIQUE FEATURES OF FURNACE

The unique features of this furnace may be summarized as follows:

The exterior is at all times at room temperature.

As soon as the metal becomes molten it is actively stirred by an automatic process.

The metal is maintained quite free from contaminating gases, and may be melted quite free from carbon.

The heated mass is heated very uniformly throughout, which makes it possible entirely to avoid metal losses which might otherwise result from the driving off of volatile constituents.

The upper temperature limit obtainable is exceedingly high. No conclusive tests on the maximum temperature obtainable have been made with a furnace of this size and capacity, but it may be conservatively stated that a temperature of 1,800 deg. C. may be obtained.

The control of the temperature is perfect, and inasmuch as the heat is generated directly in the melt the temperature will stop rising instantly when the power is much reduced or cut off.

The furnace permits changing from one kind of melt to another in the shortest possible time. The crucible which carries the melt can be slipped out of its powdered refractory and another put in its place in a few minutes. Thus any metal from one melt which remains on the walls of the crucible will not be present to contaminate the next melt when of a different material.

As all parts of this furnace except the crucible and the melt are substantially at room temperature, the essential parts of the furnace suffer little wear and are little likely to become destroyed. The construction is such that each of the parts of the furnace is easily replaced or renewed, and the construction as a whole is simple and inexpensive.

SIZES AVAILABLE AND POSSIBLE

If a sufficient supply of high-frequency power is available this same general type of furnace could be constructed to melt steel in tonnage lots. At the present time, however, the only furnace for this purpose which has been commercialized as a market product is of the size and character described in the foregoing.

USE OF THIS TYPE OF FURNACE FOR NON-FERROUS, HIGH-CONDUCTIVITY METALS AND ALLOYS

Such metals as brass, copper, gold and silver have too high conductivity to be melted with any satisfactory efficiency by direct induction. To adapt the furnace, therefore, for melting metals of this character it is only necessary to supply a crucible of molded carbon or graphite to replace, or if preferred, to fit into the crucible of non-conducting material used for melting materials of low conductivity. When the furnace is furnished with a crucible of conducting material, the heat is generated directly in the walls of the crucible, and this heat is transmitted to the metal contained in the crucible by conduction and radiation.

A furnace of the size and character described, and arranged for melting copper and energized by a standard 20-kw. high-frequency converter set will melt about 85 lb. of copper an hour, or between 600 and 700 lb. in an eight-hour day.

The theory and possibilities of heating with high-frequency currents were fully set forth by the writer in a paper read at the meeting of the American Electrochemical Society held in New York City April 3, 4 and 5, 1919, the title of his paper being "Principles of Inductive Heating With High-Frequency Currents."

The furnace which it has been the purpose of this paper to describe is only one of many types which have been developed for operation with high-frequency current. Their usefulness has been established in many laboratories and in several industrial plants.

The advantages of heating by high-frequency induction are continually being more thoroughly impressed on the minds of heating engineers. The author personally feels this application of electric methods offers more promising possibilities than almost any other development being made at the present time.

Experimental Shale Oil-Retorting Plant

AN INTERESTING development in the process of retorting oil shales is now being tested in a 15-ton commercial unit by the Shale Oil Refining Corporation, of New York, at Denver, Col., using the Johns reduction process.

The shale is first crushed and pulverized so that it passes a $\frac{1}{4}$ -in. screen and is then elevated by a conveyor to a storage gravity feed box. From this box a small portion of the material, mixed with air and non-condensed combustible gas from the retort, is forced by a blower into the combustion chamber under the retort, where it is used as a fuel.

The remainder of the pulverized product is fed into the retort and distilled. A mechanical scraping device spreads about 500 lb. of the crushed shale in a thin even layer about $1\frac{1}{2}$ in. deep over the bottom of the retort, and at the same time progressively moves the material through the retort. By this means the entering shale is subjected to the lowest temperature, and then as it moves along the temperature is increased until by the time the particles reach the hottest part at the lower end of the retort all the oil has been driven out. This process is continuous and takes about twenty-five minutes. The spent shale drops off into either a water or a dry seal and is removed by scraper belts. It may be utilized for the manufacture of brick or for other purposes.

The unit retorts are 23 ft. long, $4\frac{1}{2}$ ft. wide, about 5 ft. high in front and 9 ft. in back and are constructed with a concrete base and ordinary firebrick walls with firebrick lining for firebox and flues. The heating chamber itself extends the entire length and width of the retort and is about 9 in. high. The top is composed of angle-irons and sheet metal plates, laid in loose and covered with sand as a seal. A scraper device is also attached to the top for turning over and moving along the shale on the retort. Lugs are fitted to the top so that it can be lifted off as a unit and repairs easily made on the retort.

Carborundum tile is being substituted for the firebrick because, due to its greater heat conductivity, it

FLOW SHEET

is expected that the capacity of the plant will be increased greatly.

Take-off boxes suitably arranged at various intervals in the top of the retort are designed to carry off the liberated oil vapors to the vapor main as quickly as possible so as to minimize cracking by further heating. The vapors are then carried to the condenser, where they are cooled and crude oil obtained.

Pyrometers installed at various points enable the workmen to check and control the temperature at any desired point and thereby obtain a more uniform product.

To test certain operating conditions a number of runs have been made. One was of fifty hours duration, two of eighty hours and one of five days. In October, 1920, a test was made before the Oil Men's Convention, to demonstrate the process on a commercial scale.

Samples of distillate taken from four points—the foul main, the first and second condensers, and dry coke scrubber—after being separated from the water and redistilled were found to give a smooth flowing black

CROSS-SECTION OF OIL SHALE RETORT

GENERAL VIEW OF RETORT AND CONDENSER

oil at ordinary room temperature. According to distillation figures, 20 per cent of oil was distilled under 437 deg. F.) 80 per cent at 725 deg. F. and 92 per cent of distillation was carried on till coke formed.

The light oils taken by the absorber oil amounted to only 2 per cent of the total but, for shale oil, this light fraction is of an extraordinarily high gravity and of a low percentage of unsaturated compounds, and could be used to improve the character of the oil obtained from the condensers or else refined by itself.

A 50-ton testing plant, together with an up-to-date laboratory, is to be built by the company in the vicinity of New York City for the purpose of experimenting with oil shales shipped from foreign countries.

Sugar Exports From Cuba to the United States

The increased price of sugar accounted for the large increases in the value of the declared exports from Cuba to the United States during the past year, as compared with 1919, which are shown in the following table:

Synopsis of Recent Chemical & Metallurgical Literature

Synthetic Preparation of Humic Acids.—In the Jan. 10 issue of *Chemical Abstracts*, p. 83, there is a record taken from the *Berliner Berichte* (vol. 53, pp. 1469-76, 1920) of an achievement of leading interest contributed by Wilhelm Eller and Kaete Koch. In this they show that the deep black-brown products formed by the oxidation of phenols in alkaline solution are humic acids. It appears, however, that only such phenols yield humic acid as can, in some way, pass through a quinoid stage as an intermediate product. Thus $m\text{-C}_6\text{H}_4(\text{OH})_2$ forms no humic acid, whereas the compounds obtained from the ortho and para bodies and from quinone have the composition $\text{C}_6\text{H}_4\text{O}_3$. The proof of the identity of this oxidation product with the natural humic acids is difficult, but their physical properties and chemical reactions are such as to leave no doubt of it in the minds of the authors. They hold that there is but one humic acid, but that different phenols yield different humin substances. The nitrogen in natural humic acid is said to be due to impurities. The acid reaction of humin substances, on the other hand, is not due to impurities, but to unchanged phenolic OH groups.

Use of Aluminum for Electric Transmission Lines.—The September, 1920, issue of *Annales des Postes, Télégraphes et Téléphones* contains an important article on the use of aluminum for electric transmission lines by M. DUSAUGEY.* The author, after passing in review the history of the manufacture of aluminum and the important manufacturing concerns in Europe and America, describes the different phases leading to the adoption of aluminum in the electrical transmission industry and to the official specifications of 1913 for aluminum electric conductors. During the war a special official French commission, of which the author was one of the members, made a thorough study of the chemical and mechanical properties of the aluminum to be used and summarized the data obtained under the captions chemical composition, mechanical resistance, limits of elasticity and elongation, softeners and electric conductivity, also giving a long comparative table of the properties of commercial aluminum and copper.

A 99 per cent aluminum containing no other impurities than iron and silicon, with traces only of oxygen and carbon, gives the best practical results. He then enumerates the mechanical properties required and states that it is a very simple matter to obtain the appropriate metal which would enable the substitution of aluminum for copper in transmission cables, with a reduction in weight of half of that of copper for equal electric conductivity. He even states that for high voltage transmission lines (100,000 volts) aluminum is far more efficient than copper. Taking the weight of copper as 100, the author gives the following ratios between the weights of aluminum and copper:

For equal section of conductors.....	30 : 100
For equal heating of the conductors during the passage of the same current.....	42 : 100
For equal conductivity.....	50 : 100

The first ratio is of value especially for telephone and telegraph lines. If m is the ratio of the prices of aluminum and copper the percentage of gross economy realized by the use of aluminum is $e = 100 - 30m$.

The second ratio is of value in cases of interior conduits where the heating of the conductors plays an important part. Here the percentage of gross economy realized by the use of aluminum would be $e_1 = 100 - 42m$.

The third ratio is of value wherever electric conductors are used, and the percentage resulting from the use of aluminum instead of copper would be $e_2 = 100 - 50m$.

With copper, say, at 15c. per lb. and aluminum at 27.5c.

*L'Aluminium et son application aux lignes électriques; *Annales des Postes, Télégraphes et Téléphones*, M. Dusauguey, September, 1920, pp. 366-412.

per lb., the respective economies would be $e = 46$ per cent, $e_1 = 24.4$ per cent, and $e_2 = 10$ per cent.

The following table summarizes partially the comparisons of the different types of electric conductors.

	Commercial Aluminum	Commercial Copper	Aluminum-Steel, 7 Strands	Aluminum-Steel, 37 Strands
Specific weight, g. per c.c.	2.7	8.95	3.55	3.85
Electric conductivity (relative)	60.0	100.0	51.5	49.0
Coefficient of linear expansion	22×10^{-6}	16×10^{-6}	18.2×10^{-6}	17.25×10^{-6}
Breaking limit, kg. per sq. mm.	20	42	29	32
Coefficient of elasticity, kg. per sq. mm.	11 to 12	21 to 25	16	17 to 18
Ratio of sections for equal conductivity	1.666	1	1.943	2.05
Ratio of the diameters for equal conductivity	1.29	1	1.395	1.43
Ratio of the weight for equal conductivity	0.5	1	0.73	0.835

The article concludes with a note giving the official methods for the quantitative analyses for silicon and iron, the aluminum percentage being obtained by difference.

Determination of Silicon: A 2-g. sample is placed in a 250-c.c. porcelain dish. Add 50 c.c. of a mixture consisting of

Nitric acid, c.p. (density 1.42)	c.c. 100
Hydrochloric acid, c.p. (density 1.2)	300
Sulphuric acid, c.p. (density 66 deg. Bé.)	100
Distilled water	100

Ten to 12 minutes is required for complete solution at normal temperature. When the metal is completely dissolved add 15 c.c. H_2SO_4 , c.p. and heat until white fumes appear; cool; add 100 to 150 c.c. H_2O , boil, filter, wash free from sulphates, dry, ignite, cool, weigh. The result is SiO_2 , which is figured to silicon.

Determination of Iron: A 2-g. sample is placed in a 500-c.c. flask. Add 50 c.c. of the mixture

Hydrochloric acid, c.p. (22 deg. Bé.)	c.c. 500
Distilled water	500

Solution takes place at normal temperature or better when heated slowly. When the reaction is completed (no more bubbling) and with a pipette 50 c.c. of preventive solution consisting of

Manganese sulphate, c.p., grams	50
Phosphoric acid, 65 per cent, c.c.	100
Sulphuric acid, c.p., c.c.	100
Distilled water to complete up to c.c.	1,000

Add now 150 c.c. H_2O and titrate with a KMnO_4 solution each c.c. of which is equivalent to 2 mg. Fe.

Surface Tension and Capillary Flow.—In a paper under the title, "The Dynamics of Capillary Flow," read before the American Society for the Advancement of Science, Physics Section, Dr. Edward W. Washburn described a new, very accurate and quite simple method for the measurement of surface tension. For a horizontal tube l cm. long and of the average radius r the flow during the time t will be according to the equation

$$l^2 = \frac{\gamma \cos \theta \, r t}{2\eta}$$

where γ is the surface tension, θ the angle of contact, η the viscosity and $\frac{\gamma \cos \theta}{2\eta}$ might be called the coefficient of penetration.

The tube may be of almost any length, making the method very accurate. If there is any difference in air or hydrostatic pressure at the two ends of the tube, it must be added to the surface tension.

Statistical problems connected with the rise of liquids in capillary tubes have been investigated on both the theoretical and the experimental side, but the dynamical aspects do not appear to have received much attention.

Aside from the theoretical interest attaching to the subject, the dynamics of capillary flow have certain practical aspects in connection with the movements of water or oil through soils, the impregnation of wood and other porous materials with liquids, and the determination of the porosity and true density of porous bodies, as well as offering a new method for measuring the surface tension or viscosity of a liquid.

The rate at which a liquid penetrates a small cylindrical capillary of radius r was shown to be

$$\frac{dl}{dt} = \frac{P(r^2 + 4er)}{8\eta l}$$

where P is the driving pressure, e the coefficient of slip and η the viscosity.

The Penetration of a Porous Body by a Liquid. If a porous body behaves as an assemblage of very small cylindrical capillaries, the volume V of liquid which penetrates it in time t is given by

$$V = k \left(\frac{r}{\eta} t \right)^{\frac{1}{2}}$$

Experiments with mercury, water and other liquids verify the theoretical deductions completely.

In measuring the surface tension by the dynamic method, horizontal capillaries are perhaps the most convenient, although by using the vertical capillary immersed some distance in the liquid and allowing the liquid to drop from a point some distance beyond its equilibrium position, it should be possible to obtain good results.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Continuous Cyanamide Furnace.—Reactions between carbides and nitrogen may be carried out continuously in an annular furnace provided with an endless base plate or table. This table rotates and conveys the carbide which is placed upon it through a counter-current stream of nitrogen. Just before reaching the feeding hopper the finished material is removed by a scraper and discharged from the furnace. The carbide is preferably placed on a layer of inert substance rather than directly on the moving ring. By regulating the temperature and the flow of nitrogen, the reaction is readily controlled. (1,364,157; VICTOR THRANE, of Christiania, Norway; Jan. 4, 1921.)

Separation of Meta- and Para-Cresols.—Commercial cresylic acids contain ordinarily the three isomeric cresols in the same proportions relative to each other as they occur in coal tar. Ortho-cresol may be very completely removed from this mixture by column distillation, but since the boiling points of meta- and para-cresol are so nearly the same, chemical means must be used for their separation. Since it has been found that meta-cresol is more easily sulphonated than para-cresol, several methods have been proposed for the separation of these two compounds by sulphonating the former and removing the unsulphonated latter by means of a solvent. The residue is steam-distilled at atmospheric pressure around 110 deg. C. to break up the meta-cresol mono-sulphonic acid. According to this procedure there is present in the reaction vessel a relatively large excess of concentrated sulphuric acid at the start and a large amount of dilute acid at the finish. This is objectionable because the concentrated acid tends to sulphonate more para-cresol than is desirable and because there is a large amount of dilute acid which is unreactive which increases the cost of the operation. CHARLES R. DOWNS of Cliffside and RALPH S. POTTER of Grantwood, N. J., have discovered that by sulphonating with SO_3 in the vapor phase excess sulphuric acid is avoided and that by diluting with an equal volume of water and vacuum distilling at 70 deg. C., the unsul-

phonated para-cresol distills over. It is recovered from the condensate by extraction, cooling and centrifuging. If it is merely desired to produce a meta-cresol of 80 per cent purity, the vacuum is released and the sulphonated residue in the still is decomposed by heating to about 120 deg. C. and injecting steam. If a meta-cresol of higher purity is desired the sulphonic acid is crystallized out by cooling, filtered off and decomposed by steam. (1,364,547; assigned to The Barrett Co.; Jan. 4, 1921.)

Cyanides and Rich Producer Gas.—The following modification of the process for making cyanides by passing nitrogen over C, Na_2CO_3 and Fe is proposed by RICHARD FRANCHOT, of Niagara Falls: Gas containing 34 to 35 per cent CO is made in a slagging gas producer charged with coke, anthracite or bituminous coal as fuel, limestone as flux, and run with a hot blast so that temperatures of 1,400 to 1,500 deg. C. are reached in the hot zones. This gas is passed over balls or bricks made of magnesia 20 per cent, coke 15 per cent, soda ash 15 per cent and iron or its equivalent as oxide 50 per cent. In the reaction which ensues nitrogen combines to form alkali cyanide and the oxygen in the soda ash is converted into carbon monoxide. As a result the CO content of the gas is increased to over 40 per cent, while the temperature drops from 1,400 to 800 deg. C. The balls are leached or steamed to recover cyanide or ammonia, and re-used until they break down physically. They are then added to the charge in the producer. The iron is melted and may be collected in the usual way, while the silicates, etc., are slagged and the sodium content converted into cyanide, which volatilizes and deposits on the briquets. (1,364,838; assigned to Ferro Chemicals, Inc.; Jan. 4, 1921.)

Nitric Acid.—When sulphuric acid and sodium nitrate are mixed in a still or receptacle there occurs a violent chemical reaction, which results in a high pressure, and in the systems now generally employed this pressure often results in the loss of a large part of the gases due to portions of the system or apparatus being blown apart, and particularly blowing out the putty at the joints of the bleachers and condensers. This difficulty may be overcome by the use of an expansion chamber of 14 in. chemical ware or Duriron pipe, into which the gases from the battery of twenty stills are allowed to escape and mix freely. This results in a more even flow of gas to the bleachers—five in number—in which the acid flowing down from the condensers is bleached by the action of the hot gases about to enter the condensers. (1,361,416; CHARLES L. TAYNTOR, of Claymont, Del.; Dec. 7, 1920.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Non-Fragile Glass.—Non-fragile glass, which can be rolled, forged, extruded, cast, etc., is made by dissolving in the dry state such silicates as micaceous or asbestos minerals in molten glass or similar silicate. The glass, etc., is chosen so as to melt at a temperature below the temperature at which the mica, etc., effloresce. If the product is to be machined, an excess of mica, etc., should be present over the amount required to form a saturated solution. (Br. Pat. 152,780. P. B. GROSSLEY, Calcutta, India; Dec. 31, 1920.)

Purification of Zinc.—In the purification of zinc solutions, and in particular the preparation of zinc solutions for electrolysis, silica is separated in a filterable form by adding an alkali or alkaline earth carbonate in slight excess to the neutral or substantially neutral liquor, at an elevated temperature. In an example, a ground zinc sulphide ore is roasted to convert to oxide and sulphate and then after re-grinding is added to hot sulphuric acid of 10 to 15 per cent strength, which may be that obtained from the electrolytic cells. When the acidity has been reduced to 5 per cent, it is still further diminished to 1 per cent by the addition of a mixed precipitate of zinc oxide and carbonate and iron oxide, obtained in a subsequent stage in the purification. Neutralization is finally attained by adding whitening in the form of powder or of a milk made with water. The silica is then precipitated by adding about 10 lb. of whitening per ton of liquor and maintaining the tempera-

ture at 90 to 100 deg. C. for a short time with agitation. After filtration, the silica is washed with water to free it from zinc. (Br. Pat. 152,752. F. PETERSON and METALS EXTRACTION CORPORATION, London; Dec. 31, 1920.)

Coating With Copper.—A copper-salt solution is reduced by hydrazine hydrate in the presence of ammonia, the copper being deposited as a coherent coating on heated, non-conducting, smooth or polished surfaces, such as glass, china, porcelain and the like, in contact with the solution. The coating liquid can be prepared by adding strong copper sulphate solution to a strong solution of hydrazine sulphate in hot water until a faint blue color persists on standing and a pale-blue powder is precipitated. If not for immediate use, the powder may be filtered and dried. When used, it is suspended in cold water, a few drops of cold hydrazine sulphate solution added, followed slowly by a solution of ammonia until the liquid turns dark brown, when caustic soda solution is added until a slight yellow or orange precipitate persists after shaking. The precipitate is dissolved by a little hydrazine sulphate, yielding the clear yellowish or brownish liquid required. (Br. Pat. 152,835. J. D. SMITH, The University, Birmingham; Dec. 31, 1920.)

Ultramarine.—Sulphites or bisulphites of the alkalis or mixtures of these salts are used in the manufacture of blue or green ultramarines to replace wholly or partially the alkali carbonates or sulphates usually employed. The sulphite of soda obtained as a byproduct in the preparation of phenol is particularly suitable for this purpose. In an example, the furnace charge consists of kaolin, sulphite of soda, sulphur and a reducing agent such as resin. (Br. Pat. 152,916. J. B. GUIMET and A. GUILLOCHIN, both of Fleurien-Sur-Saone, Rhone, France; Dec. 31, 1920.)

Purifying Ammonium Sulphate.—The coloring matter usually associated with crystals of ammonium sulphate is removed by agitating the latter, in a detached condition in a clear saturated solution of that salt, maintained slightly acid—if necessary by the addition of sulphuric acid—and floating of the suspended impurities. The agitation may

be performed mechanically, or by blowing with air or steam, but preferably it is effected by means of the saturated ammonium-sulphate solution, which enters at a point near the bottom of the conical-shaped treatment vessel containing the crystals. The rapid stream on entering stirs up the crystals, but as the diameter of the vessel increases

only the impurities remain suspended. The accompanying figure shows the saturator A from which crystals are removed to the vessel C by means of steam lift B. A stream of filtered saturated ammonium sulphate enters by pipe d, and is regulated by valve r. The temperature of the liquor throughout the system is maintained at the same temperature as the crystals coming from the saturator by means of steam coils in the storage tank D and the filter F. The clean crystals are discharged periodically on to the drainer H, the liquor collecting in the sump G, from which it is raised to tank D by means of an air lift. An ordinary saturator may also be adapted for the process. Crystals having been deposited, the passage of ammonia is reduced or stopped. A filtered saturated solution of sulphate of ammonium is supplied near the bottom of the saturator and overflows through a launder and passes to the filter as previously described. (Brit. Pat. 152,766. R. LESSING, London; Dec. 31, 1920.)

Treating Zinc.—Finely divided zinc or zinc dust for use in the purification of zinc solutions prior to electrolysis, for precipitating metals from cyanide or other solutions and as a reducing agent in the preparation of organic compounds is treated with a view to increasing its activity. The zinc may be stirred with boiling water or with a solution of an alkali such as caustic soda. (Br. Pat. 152,997; not yet accepted; ELECTROLYTIC ZINC Co. of Australasia Proprietary, Melbourne, Australia. Jan. 12, 1921.)

Current Events

in the Chemical and Metallurgical Industries

American Ceramic Society to Meet in Columbus

The program of the twenty-third annual meeting of the American Ceramic Society, which occurs at the Hotel Deshler, Columbus, Ohio, Feb. 21 to 24, is on the press and will shortly be in the hands of members.

Nearly twice as many acceptances as last year have been received by the secretary, and over one hundred papers are on the program. The Divisions of Enamels, Glass, Refractories and Terra Cotta will have separate meetings on Tuesday, Feb. 22, with divisional papers. At the same time conferences will be held, with informal discussion, of three groups—Decorative Processes, Heavy Clay Products and White Ware—with a view to the formation of divisions.

The local committee is making attractive plans for entertainment. Section Q, on Monday evening, is open to members and guests, and the events of the evening are shrouded in secrecy. Nobody knows what is going to happen, therefore everybody will be present to find out. The banquet will be held in the spacious ball room of the hotel on Tuesday evening. Special plans are being made for the entertainment of ladies who accompany members.

Department of Agriculture Criticizes Use of Poison Gas for Boll Weevil Control

For the past eight months the Chemical Warfare Service has been engaged in a conscientious effort to be helpful in the matter of boll weevil control. The chemists connected with the Chemical Warfare Service are hopeful that war gases can be used to the benefit of the cotton growers, who suffer losses aggregating hundreds of millions of dollars each year, due to the ravages of the boll weevil. The Department of Agriculture not only has no faith in the successful outcome of the experiments being conducted by the Chemical Warfare Service, but on Feb. 9 issued an official statement the effect of which was to ridicule the idea of any such use of poison gases. Officials of the Chemical Warfare Service resent this attitude on the part of the Department of Agriculture. The statement was issued without conferring with the Chemical Warfare Service and without any effort having been made to ascertain what that branch of the Government service had done in the way of experimentation. As a matter of fact, the work had reached a point where it was being carried on jointly by the C. W. S. and the Agricultural Department of Georgia.

The Department of Agriculture took particular pains to deny a published statement to the effect that the work is being carried on in co-operation with it. It is true that no co-operative contract exists between the two federal agencies, but before embarking upon the experiments, the chief chemist of the Warfare Service conferred with the specialists of the Bureau of Entomology and was assured that they always stood ready to help any plan which had as its object a more effective control of the boll weevil. Supplied with data from the entomologists which would prevent duplication of any work that had been done, the Chemical Warfare Service proceeded with its experiments. No claims have been made for any successes, but when the proper time comes it is admitted that there may be something of a surprise in store for even the department which has been working on this problem with rather qualified success for a long period of years.

Fertilizer Report Soon

A comprehensive report on the fertilizer situation will be made to Congress soon by the Bureau of Soils of the Department of Agriculture. The report is being made in response to a Senate resolution and will contain comment as to prices and the general fertilizer situation.

Approved Patents for Government Employees

The conferees on the Patent Office bill have reached an agreement which includes the proposal that the Federal Trade Commission administer patents issued to Government employees. The conferees also agreed upon the salary scale approved by the House. The Senate made material reduction in this salary scale, but the conferees approved the higher salaries. In fact the bill, as passed by the House, was approved in almost all particulars. The real point of issue in the conference was the retention of the Government employee patent feature of the measure. No opposition of consequence is expected when the conference report is brought up for acceptance. The bill provides important revisions in the procedure in the Patent Office. The section referring to the handling of Government employee patents reads as follows:

That the Federal Trade Commission be, and hereby is, authorized and empowered to accept assignment of, on behalf of the United States, under such regulations and in such manner as the President shall prescribe, inventions, patents and patent rights which said commission deems it to the advantage of the public to be so accepted, as these may from time to time be tendered it by employees of the various departments or other establishments of the Government except employees of the Patent Office, and to co-operate, as necessity may arise, with scientific or other agencies of the Government in the discharge of the duties herein set out, and the Federal Trade Commission is hereby authorized and empowered to license and collect fees and royalties for licensing said inventions, patents and patent rights in such amounts and in such manner as the President shall direct, and shall deposit the same with the Treasurer of the United States; and of the total amount of such fees and royalties so deposited a certain per centum, to be determined by the President, shall be reserved, set aside and appropriated as a special fund to be disbursed as directed by the President to remunerate inventors for such of their inventions, patents and patent rights contemplated by this section as may prove meritorious and of public benefit. Provided, That nothing herein shall be construed to give to said commission or any other governmental agency any authority to engage in the manufacture of any such invention or patented article.

The Commissioner of Patents is hereby directed to grant all patents and record all assignments and licenses contemplated by this section without the payment of any fee.

Symposium on Corrosion

At the coming Atlantic City meeting of the American Electrochemical Society (April 21 to 23) one of the sessions will be devoted to a symposium on Corrosion—in particular, electrolytic corrosion. Among those who will participate are Messrs. A. S. Cushman, D. M. Buck, W. H. Walker, James Aupperle, H. S. Rawdon, F. N. Speller, O. W. Storey, Richardson, Shephard and Gardner. Although most of the discussion will be concerned with the corrosion of iron and steel structures, a number of the papers will be devoted to the disintegration of lead and other non-ferrous metals. The subject of corrosion has been growing in importance owing to the ever-increasing number of electric railway installations, buried cables, metal roofings and inclosures, large metal gas holders, storage tanks, etc. Corrosion is the one topic that interests men of almost every profession: the architect, the electrical engineer, civil engineer, metallurgical and chemical engineer, railroad engineer, surgeon, dentist, paint-chemist, geologist, etc. The Electrochemical Society's symposium on the subject will be the most complete yet organized.

Kiln Drying Course at Forest Products Laboratory

The February course in practical kiln drying will be given at the Forest Products Laboratory, Madison, Wis., Feb. 14 to 25. Instruction in these courses is not confined to any particular kind of kiln, although methods of drying different species of lumber and operation of various types of kilns are discussed. Emphasis is laid on the underlying principles of successful kiln drying and these can be adapted to any conditions. This course will be conducted much like the preceding ones, which have proved more popular than was expected.

Meeting of the American Ceramic Society, Chicago Section

The Chicago Section of the American Ceramic Society met at the City Club on Saturday, Feb. 5, for luncheon and subsequent technical program.

D. T. Sweely, of the Coonley Manufacturing Co., presented a paper on the acid resistance of enameled cooking utensils, which consisted of a series of notes to be given in more detail at the annual meeting of the Ceramic Society in Columbus this month.

Lester T. Wilson, superintendent of the Chicago plant of the National Lead Co., gave an interesting talk on the manufacture of lead products used in the ceramic industry. He described briefly the course of lead from the ore at the mines to the finished product, with references to the old Dutch, Carter and Lennox processes of making white lead and the methods of manufacture of red lead and litharge.

Of all the products which the ceramist purchases for his glazes nothing is perhaps more pure than lead, which has an average purity of 99.96 per cent. The copper content is always low, because copper alloys with lead in the proportion of 0.001 per cent only. The iron found in lead products, which is of course detrimental to the glazes, usually comes from the machinery in which the material is ground. Since the ceramist is interested chiefly in the actual metallic lead content of compounds, he should be careful to compare his market rates in determining whether to purchase white lead, litharge or red lead. The methods of determining weight per cubic inch in lead compounds is not a good test for determining the settling rate of the material in glazes. What the ceramist should determine is the real specific gravity.

The ill effects upon workers with lead are usually greater in plants using lead products than in lead manufacturers' institutions, because the latter realize the danger and take the necessary precautions. The lead industries have practically been legislated out of France and it is interesting to note the present legislation in the United States. There are many means for preventing lead poisoning, all of which the lead producer will gladly make available to the user of the product.

A resolution was passed at this meeting to call to the attention of the American Ceramic Society at the Columbus meeting the necessity for requesting the Lead Institute to furnish all ceramists with necessary information for preventing lead poisoning in clay-working plants.

X-Rays in Industry

Dr. John S. Shearer, of Cornell University, addressed the Connecticut Valley Section of the American Chemical Society in Waterbury, Feb. 5, speaking on "Some Recent Applications of X-rays in the Study of Metals."

In the course of his talk Dr. Shearer sketched briefly the history of the development of our knowledge of X-rays from the time of their discovery a quarter of a century ago. This development, he said, was twosided; on one hand the constant improvement in apparatus culminating in 1913 with the Coolidge hot cathode tube; on the other, a growing knowledge of the laws governing this powerful aid to science, also culminating in 1913 with the work of Laub, who was the first to go beyond studying X-rays by means of absorption.

With powerful sources of X-rays to work with and with the use of crystals for diffraction gratings, thereby rendering it possible to know the positions of atoms in the molecule, a tremendous advance in the study of the fundamentals became possible. Advance in this direction has hardly begun. Phenomena depending upon atomic arrangement, such as amorphous films, surface tension, self-annealing, season cracking, dispersion of excess constituents, may evidently be studied directly with the X-ray, thus securing data which will prove or disprove many accepted theories based only on inference.

Dr. Shearer did not believe that the X-ray would ever become valuable as an instrument for control work, but it has great possibilities in the perfection of processes and study of causes of failure with an eye toward their re-

moval. It is important to note that its use does not injure the specimen.

During the war X-rays proved valuable in investigating the condition of loaded rifle shells. It was possible to check up on the performance of the loading machinery and tell whether or not it was functioning properly; also jacketed bullets could be tested.

Not only metals but wood can be examined. The grain of wood shows up very clearly in an X-ray photograph, and varnish or any other protective coating makes no difference. Consequently the X-ray was used to some extent in airplane construction inspection to see that inferior woods were not substituted for spruce.

In conclusion Dr. Shearer warned his hearers that there were two sources of danger in the use of modern X-ray apparatus: the high tension current used for generating them and the rays themselves, for X-ray burns are quite serious. On the practical side great difficulties must be overcome before X-rays can become useful except in especially trained hands. There is no "foolproof" source of them yet developed.

Research in Explosives and Nickel

Some benefits to industry resulting from research scientifically conducted were interestingly stated by Dr. Charles L. Reese, chemical director, E. I. du Pont de Nemours & Co., and A. J. Wadhams, general superintendent, International Nickel Co., in addresses before the Division of Engineering of the National Research Council on Friday, Feb. 4, at the Engineers' Club, New York.

Dr. Reese emphasized the value to industries of organized research in particular. Some research projects are not immediately productive of financially profitable returns, others yield great savings or large profits immediately. If research be properly organized, or conducted on a co-operative basis by one great industry or a group of industries, a winning average from the accountant's method of keeping score is much more likely to be made. Organization and co-operation, however, must be so conducted that the individual research worker feels no restraint.

Mr. Wadhams told of the hurdles research had to take successfully in order to become established in old industrial plants. Three groups particularly required "converting" the directors, the shop superintendents and the foremen. Success depends largely upon the human qualities of the research personnel and their ability sincerely to recognize the value of the knowledge gained by the practical man in his experience, as well as the knowledge of the laboratory.

Galen H. Clevenger, consulting metallurgist, U. S. Smelting & Refining Co., Boston, presided at the meeting of the Division of Engineering, at which there were present twenty-two members and guests, men of high standing as research specialists or executives in leading industries. The Division's work is directed toward stimulation of research in the industries and bringing about co-operation in the acquisition of new scientific knowledge and its dissemination among engineers and managers of our industries. The division is supported by the National Research Council and by Engineering Foundation, representing the great national societies of Civil, Mining, Metallurgical, Mechanical and Electrical engineers.

Chemists Oppose Packers' Bill

Information reaching Washington is to the effect that manufacturing chemists, as a rule, are opposed to the bill for regulating the packing business. While sentiment among them is thought to be against any expansion of federal regulation of private business, there is a particular reason in the case of the packer bill, since the control is extended to the byproducts of the packing industry. A strict interpretation of the bill probably would enable this federal control to ramify into the fertilizer industry and other chemical activities using any of the byproducts of the packing industry.

The Haugen bill is regarded as being much more desirable than the Kenyon bill, which was passed recently by the Senate.

Dr. Smith Speaks on "Research"

A joint meeting of the New York Sections of the American Electrochemical Society, American Chemical Society, Society of Chemical Industry and Société de Chimie Industrielle was addressed by Dr. Edgar F. Smith Friday, Feb. 11, at Rumford Hall.

Dr. Charles A. Doremus presided. In his introductory remarks he made allusion to the work done by Dr. Smith as a historian of the early American chemists, and outlined some of the activities of James Woodhouse, founder of the first chemical society in America, and of Robert Hare, who did great pioneer work in electrochemistry. He compared this work to that of Benjamin Franklin and showed that the experiments of these two great American philosophers have been of the greatest importance to the development of applied science.

Dr. Smith gave a very interesting talk on "Research," in which he stated that research is a great work, but that to do it successfully the chemical investigator needs to be armed with sound preliminary education in general chemistry and other academic studies so as to enable him better to correlate the results of his work.

Tariff Free List Under Consideration

Consideration of the free list schedule of the tariff bill was begun by the Ways and Means Committee of the House of Representatives on Feb. 11. Many of the raw materials used by chemists are included in this schedule. If these raw materials are to be removed from the free list and made dutiable, it will be necessary to revise the duties asked on manufactured chemicals, since the cost of production would be enhanced by a duty on raw materials.

Since the interest in the articles on the free list is mostly of an individual character, there was concerted action among the manufacturing chemists on comparatively few items. The opposition to a duty on iron pyrites, however, was unified. Since sulphuric acid is such a basic material, the consensus was that pyrites should be continued on the free list.

All Hope for Nitrogen Corporation Bill Dies

Senator Underwood, who championed the bill authorizing the establishment of the U. S. Fixed Nitrogen Corporation, which was passed by the Senate recently, admits that there no longer is hope for the final approval of the bill at this session of Congress. Opposition to the measure in the House was sufficiently strong to prevent its being brought to a vote in the lower chamber. Senator Underwood remarked, however, that the proposal to keep the nitrate plants at Muscle Shoals in stand-by condition is untenable and that sooner or later Congress will be forced to make some disposition of them.

Senator Underwood was successful in his effort to obtain the adoption by the Senate of an amendment to the sundry civil bill appropriating \$10,000,000 for continuing the work on the Wilson dam. It is regarded as probable that this item can be held in the bill, despite the fact that the House refused to amend the bill to that effect.

New Haven Section, A.C.S., Elects Officers

At the annual meeting held Jan. 28 at the Graduates' Club the New Haven Section of the American Chemical Society elected the following officers for the ensuing year: President, Dr. H. Hibbert; vice-president, Dr. M. C. Burt; treasurer, J. L. Christie; secretary, Dr. Blair Saxton; councillor, W. R. Hibbard.

At dinner the members gathered in Kent Laboratory when Dr. S. F. Acree, of Hahnemann Hospital, Rochester, N. Y., delivered a very interesting address on "The Measurement and Significance of Hydrogen Ion Concentration in Chemical and Biological Work." He exhibited his apparatus for determining hydrogen ion concentration, and illustrated his lecture by showing titration curves for pure acids, buffer solutions and extracts such as those from flour, cornmeal and chestnut bark. He pointed out various problems in which hydrogen ion concentration is an important factor. Among those mentioned were bacterial growth, tanning, inversion of sugar, electroplating, precipi-

tation from water solution, plant growth and soil acidity and the growth of chestnut blight and the acidity of bark extract. He further brought out how titration curve may be analyzed back and the acids present in a solution identified. This might prove useful in the study of the decomposition products of such substances as the protein.

Dr. Acree also showed samples of standardized standard indicator and buffer tablets which have proved to be of great convenience, especially to bacteriologists.

Book Reviews

APPLICATION OF DYESTUFFS. By J. Matthews, Ph.D. Pp. xvi + 768; 303 figures. New York: John Wiley & Sons, Inc., 1920. Price \$10.

This volume is an outgrowth of the author's earlier book "Laboratory Manual of Dyeing and Textile Chemistry." It has retained the text-book feature, but has been broadened in scope and detail. A feature of the book is the large number of illustrations of machines that find application in the treatment of the textile fiber from the raw material to the finished product. Emphasis is placed on the dyeing of textiles and particularly the processing of the most important fibers, wool, cotton and silk.

The general scheme of the book is first to study the action of various chemical agents on the fibers and methods of scouring and bleaching them preparatory to dyeing. The dyes are then classified from the standpoint of their application to the fibers. Each class is then presented in detail sufficient to explain the general methods of application and the chemistry underlying the process. No attempt is made to consider dyestuffs from their chemical classification. That dyestuffs are important to many industries that color their products is shown in the use of dyes for coloring of leather, paper, printing inks, etc.

One will find information on the equipping of a laboratory and methods of testing dyes for strength, etc. The history of dyeing, theory of dyeing, dyeing of mixtures of animal and vegetable fibers, methods of textile chemistry, tables of specific gravities and other information regarding the materials of the dyer and an extended bibliography round out the volume.

There is a wealth of general information presented, mention, at least, being made of almost every method of dyeing or related processes that are likely to be used. Only generalizations can be made, as each phase is capable of becoming a highly specialized one. Dyestuffs are individualistic in their properties, and methods of application must change as the materials that are being processed change. Practical contact must be had for a thorough understanding. The book, however, should prove valuable to all those interested in application of dyestuffs or related processes, especially in the textile industry. For the student there is a list of experiments at the end of the chapters that point out the main facts that need emphasis. ELMER C. BERTOLET.

EMINENT CHEMISTS OF OUR TIME. By Benjamin Harrow, Ph.D. New York: D. Van Nostrand Co. Price \$2.50.

Dr. Harrow, who is associate in physical chemistry at Columbia University, has written a book that was much needed. We need tags for our great men in chemistry. They have done important things, and the world should know them by name. But it doesn't. Their work is very arduous; it calls for such intense application that few of them are known in affairs. They do not grow rich save in rarely exceptional cases, and therefore they do not build palaces or give social parties that are remembered—like the Bradley Martin ball of a generation ago.

In the present volume Dr. Harrow has with great diligence prepared monographs on the following eminent men: Sir William Henry Perkin, Mendeleef, Sir William Ramsay, Theodore W. Richards, van't Hoff, Arrhenius, Morrison, the Curies, Victor Meyer, Ira Remsen and Emil Fischer. At the end of each chapter there is a list of references from which he obtained his information.

As records the monographs are excellent, and the book is enriched with full-page likenesses of each of the subjects treated. It was written for the general public rather than for chemists alone, and while it would have made the work unwieldy if complete lists of the works of the various leaders were given, the author has emphasized the leading contributions of each.

Our only criticism is that the author has not studied his various subjects with such enthusiasm as to give a more intimate touch to his work. We know about the men after reading the several essays, but we do not feel that we know them. There are not many short, fat, tell-tale sentences such as that in regard to the Russian who, on meeting Sir William Ramsay, said, "I am Mendeleef!" That "I am" is significant and explains the difference between Mendeleef and Newlands, and why the former was indifferent as to whether other chemists laughed or cried over the Periodic Table, while the jeers of his fellow members of the Chemical Society of London caused poor Newlands to give it up in despair. We miss the abounding good fellowship of Sir William Ramsay, the subtle refinement and social grace of Theodore Richards, the flirtatious days of van't Hoff as a student, and the persistent flutter of young feminine hearts about him, the joy of companionship which Arrhenius bestows, or the amazing beauty of Victor Meyer as a young professor at Zurich with his singular resemblance to the Christ-face of the Renaissance painters.

These, however, are mere details. Dr. Harrow gives more important information, and the book is at once readable and is enlivened by a number of happy anecdotes. It "belongs" in every chemist's library. ELLWOOD HENDRICK.

Personal

W. E. BURKHARD, formerly chemical engineer with the Perth Amboy Chemical Works, is now chemical engineer with Clark, MacMullin & Riley of New York.

E. K. CHASE, assistant superintendent of the Pueblo plant of the American Smelting & Refining Co., is recovering from appendicitis and leaves for California soon to recuperate.

R. E. DEMMON has been transferred from the main office of the Stauffer Chemical Co. to the Houston, Tex., office, where he is general manager. The sulphur refinery of the company is at Freeport, Tex.

WALTER S. ERNST has recently resigned as chief chemist from the Ironton plant of the Alpha Portland Cement Co. to enter the University of Alabama as a student in the chemical engineering college.

A. E. MACARTHUR, formerly chemist at the Durango plant of the American Smelting & Refining Co., has been transferred to the Pueblo plant to organize and operate the salvage department.

O. E. RUHOFF, formerly chemical engineer for the French Battery & Carbon Co., Madison, Wis., has severed his connection with that company in order to associate himself with the Industrial Research Laboratories of Chicago.

Dr. JOHN E. SCHOTT has recently been appointed assistant professor of chemistry at Pennsylvania State College, State College, Pa.

HOMER STALEY, of the Metal & Thermit Corporation, is spending several weeks in Chicago working out problems at the plant of the company.

MAX SELTZER, who was formerly connected with the Research Laboratory of Applied Chemistry at the Massachusetts Institute of Technology, Cambridge, Mass., is now chemist for the Interstate Chemical Co., of Jersey City.

Dr. CHARLES WADSWORTH, who has recently become affiliated with the Grasselli Chemical Co., is carrying on some special research work at the Chicago plant.

M. M. WOOD is now employed as chief chemist by the Little Rock Picron Industrial Co., Little Rock, Ark., which purchased the picric acid plant built by the Government.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Feb. 14, 1921.

Inquiries of a miscellaneous nature kept the chemical market in an irregular condition during the past week. Business in general was interrupted now and then by intervals of dullness and it appeared that consumers were still doing more meditating than operating. This condition is the result of the acute downward revision of values and the fact that not enough confidence in the future has been restored to instill a more optimistic spirit in the purchasing of materials on a large scale. Compared with the beginning of the year, however, conditions seem more improved and activity shows some expansion. There is no doubt that business is due to become better, but it looks as though the increase will be along gradual lines. Reports of a general improvement were heard from some of the leading textile mills which are distinctly favorable factors for the chemical market. A steady increase in activity was noted from shoe and leather factories, and paper mills were disposing of their stocks at recently reduced prices. The soap industry has shown a somewhat irregular condition, but indications are more favorable than at the beginning of the year as far as activity is concerned.

Quite a satisfactory amount of small lot business was placed during the week. Some large inquiries were also noted in the market, but the wide differential in manufacturers' and second-hand prices had a restraining influence on the consummation of any big business. Several of the smaller chemicals were reduced in price. Such items as cobalt oxide, fluoride of soda, white granular sal ammoniac, prussiate of soda and cream of tartar have sold at lower prices on the spot market. The big items have shown a steadier tendency with the exception of bichromate of soda, which suffered from second-hand competition and closed with a loss of $\frac{1}{2}$ c. lb.

GENERAL CHEMICALS

Resale *bichromate of soda*, standard make, was offered at 8 $\frac{1}{2}$ c. per lb., with odd lot sales reported down to 8 $\frac{1}{4}$ c. The tone of the market appeared rather easy under pressure of resale stock through second hands. Demand was quiet and confined mostly to small lots. Dealers quoted March shipments at 8 $\frac{3}{4}$ c. per lb. Resale lots of *bisulphite of soda* were on the market at 5 $\frac{1}{2}$ c. per lb. against an inside figure of 6 $\frac{1}{4}$ c., which was named by some producers. The demand cannot be termed active, although small lot sales for actual consuming wants were passing. General quotations for resale solid *caustic soda* remained at \$3.85@3.95 per 100 lb. Odd lots of standard material could be purchased at 5 c. per 100 lb. below the general figure. Contracts were held firm by leading producers at \$3.60 per 100 lb., basis 60 per cent, f.o.b. works for prompt and future shipments. Trading was not very lively, although a moderate exchange of carlots was reported among dealers. American *cyanide of soda* is holding steady under limited offerings. Leading producers quote the market at 29 c. per lb. and it is doubtful if any small lots can be purchased under this price in any second-hand quarters. The French is quoted at 20 c. per lb., while Cassell's English is held at 25 c. Sellers of German quote the market at 21@23 c. per lb. according to strength.

Spot prices of *nitrite of soda* have been subjected to considerable irregularity during the past week. Some of the largest dealers have advanced their price to 9 c. per lb., while small lots on spot were obtainable all the way down to 6 c. A moderate improvement from domestic consumers was reported. *Prussiate of soda* closed easy with sellers asking 16 $\frac{1}{4}$ c. per lb. Forward shipments were offered at 15 $\frac{1}{4}$ c. per lb. The demand was quiet in the final trading and a keen state of competition existed among dealers. Light *soda ash*, in barrels closed firm at 2 $\frac{1}{4}$ c. per lb. ex-store N. Y. A fair inquiry was reported for this material in

cooperage, but the resale offerings were small. Single bags were quoted at \$2.05 per 100 lb. Double bags were quiet and rather nominal at \$2.20 per 100 lb. Contract prices remained firm at \$1.72½ per 100 lb., basis 48 per cent, f.o.b. works.

While odd lots of domestic *caustic potash* are floating around the market at 14c. per lb. through second hands, there are sellers of 88-92 per cent KOH imported material at 9c. per lb. laid down in N. Y. The irregularity in price of late has dampened any large buying interest except for actual necessities. Large producers have not announced any new prices so far this year. Spot *oxalic acid* closed firm with 18c. lb. as an inside figure by second hands. In most quarters the market was quoted above this level and the extreme price range is up to 25c. per lb., according to brand and seller. Shipments from abroad were offered at 17½c. in some directions. Enough white granular, high-test *sal ammoniac* is being dumped into the open market to depress prices. There were sellers at the close of the week at 7½c. per lb. The inquiry for this material has not been active of late and there is a keen state of competition existing among holders of imported material.

COAL-TAR PRODUCTS

Appearances during the week in the coal-tar products markets were mostly of an encouraging nature and while here and there an easy tendency was noted, the bulk of the various factors held views that reflected firmness. Activity varied from day to day and during the close of the week the interest of buyers slacked off somewhat and offerings did not attract the same attention. Buyers, however, were in close touch with the market and were ready to pick up any real bargains.

The *naphthalene* season is at hand and speculative buying of the off grades was noted in some directions. The pure white flakes were held firm and the best offering that could be located was at 8½c. per lb. Producers continued to quote 9@10c. per lb. on flakes and 11c. on balls. During the early part of the week *aniline* was fairly steady at 21@26c. per lb., although a lot here and there was offered at 20c., while at the close a seller of a round lot was calling for bids. Supplies of *dimethylaniline*, *beta naphthol*, *para nitraniline* and *para toluidine* were easy and shading in second hands was possible.

Producers of *alpha naphthalamine* continued to quote steady at 40@45c. per lb. Supplies in second hands are reported available in fair volume and with the demand light prices were heard at 38@40c. per lb. Trading in *dinitro chlorbenzene* is reported as quiet with only a light routine movement. Supplies are easy on a basis of 25@30c. per lb., while in second hands shading on firm business is possible. The market in *salicylic acid* is not very active at this time and only small lots are moving into consuming channels. There has been no recent change in prices, which range from 25@30c. per lb. Trading in the market for *para toluidine* is dull with most factors taking care of a moderate routine call which is about sufficient to meet consumers' immediate needs. Prices vary somewhat, depending on sellers, and range from \$1.40@\$1.70 per lb.

RUBBER—WAXES

The crude rubber market was easier during the past week, but toward the close a reaction was noted with higher prices named. Spot ribbed smoked sheets opened at 18½c. per lb. but declined to 17½c., the lowest of the week. At the close, however, a firmer tone developed and prices advanced to 18c. with a few small sales recorded at 17½@17¾c. per lb. Sales of first latex occurred at 19½c. per lb., while sellers were asking 19¾c. March ribbed advanced to 18½c. April, May, June was quoted at 21c. by holders and buyers at 20½c. per lb., but as far as could be ascertained no business was done. For July-December, sellers named 26c. per lb. and buyers 25c. Trading in general was of a small volume, as consuming manufacturers continue to be practically out of the market.

Importers of African and Brazilian *beeswax* reported market conditions as unchanged with prices on a fairly steady basis. African crude wax in carlots was offered at 17½@18c. per lb. for immediate shipment. Brazilian crude

wax was held at prices ranging from 24@26c. per lb. Trading in refined was along routine lines only and prices were more or less nominal. A moderate buying interest was noted for the lower grades of *carnauba wax* and prices closed for the week practically unchanged both in prompt and forward business. The high grades on spot continued in light supply. No. 2 North Country was quoted at 33@35c. per lb., while No. 3 was unchanged at 18@19c. per lb. Spot offerings of *Japan wax* were moderate and prices ruled steady ranging from 19@20c. per lb. Shipment prices showed little change and the situation was regarded as favoring sellers so far as the near future was concerned. Offerings of both crude and refined *paraffine wax* continued on a liberal scale and prices throughout the week were unsettled, the undertone being easy. Export shipments against old contracts were fairly large but new business was reported as dull in nearly all directions. Crude wax, 124-126 deg. melting point, was available in a large way at 4c. per lb., with intimations that this figure could be shaded on a firm bid. Refined, 128-130 deg. melting point, was available at 6½c. per lb.

The Iron and Steel Market

PITTSBURGH, PA., Feb. 11, 1921.

The finished steel market has suddenly started to break. There is not the gradual subsidence that was expected in most quarters, but rather a sharp drop, whereby in a very short time a level will be found that will prove relatively stable, at least until costs can be reduced.

It will be recalled that the steel market of the independents dropped to the Steel Corporation or Industrial Board level in the closing weeks of the old year, bars, shapes and plates showing their drop the day after Thanksgiving Day. A common expectation then was that the independents would promptly begin shading the regular prices by small amounts, whereby in time the market might slowly subside. This expectation was not borne out. Many independents did not cut at all, while others who were disposed to make slight concessions found there was scarcely any business to be obtained that way.

Thus a situation was presented. The Midvale Steel & Ordnance Co. decided to canvass the trade for orders, offering substantial concessions. The canvass occupied a few days, with the other independents watching. Apparently their philosophy at the time was that if the cutting produced much business they would participate and if it did not they would remain aloof. It did not produce much business. Then, it appears, the other independents altered their viewpoint and concluded that the test showed that eventually very substantial reductions would have to occur and that they might as well meet this situation at once. Accordingly a large number of independents yesterday became willing to make substantial reductions, the amount to be determined by the tonnage obtainable and the possibility of avoiding loss either against previous costs or such costs as could be developed by further economy.

FINISHED STEEL MARKET DECLINING RAPIDLY

The finished steel market has accordingly been declining rather sharply in the past couple of days, and there are no prices that are sufficiently fixed to be quoted as the market even for a day. For illustration, merchant steel bars, which had been 2.35c., sold in some fair sized lots at 2.25c., then in a small lot at 2.20c., with possibly some sales at 2.10c., while the latest is that one mill has adopted 2c., not quoting the price openly but being ready to take any order of reasonable size and fair specifications at that figure. In structural shapes 2.25c. has been named, or \$4 a ton decline, without any business of importance developing. Plates had been selling at times for weeks at 2.50c., against the Industrial Board or Steel Corporation price of 2.65c., while in the past few days 2.40c. has been done and quite probably less.

It is of no moment just where the market stands at the present writing. Enough is known to permit a guess to be hazarded as to the approximate level the heavy rolled products will develop in the present movement. The level is about 2c. Shapes will probably be about \$2 a ton above

bars, and plates may not be as much above bars. Before the war plates and shapes averaged quite closely \$2 a ton above bars, but with the large plate-making capacity now in existence a smaller spread may obtain. Until now plates have preserved much of the spread above bars and shapes that the war-time regulation furnished as an incentive to plate manufacture, the war control prices being 2.90c. for bars, 3c. for shapes and 3.25c. for plates.

CONCESSIONS IN SHEETS

Concessions thus far announced in sheets represent about \$3 a ton, outside of prices made by some mills at a distance from Pittsburgh, representing concession of part of the freight advantage. As the system of Pittsburgh basing has not been expected to stand in a period of active competition, such special prices cannot properly be figured back to Pittsburgh and the claim made that the Pittsburgh price itself is cut by the amount shown. In wire products it is not known that more than one producer has departed from regular prices, it being stated that one producer east of Pittsburgh is naming \$3.10 on nails, against the regular price of \$3.25.

NO REDUCTION BY STEEL CORPORATION

The United States Steel Corporation has made a formal announcement that it will not reduce prices or wages, but it would be impossible to name a time for which such a statement would hold good. Such curious views have been spread as to business and economics that the statement may be misinterpreted in some quarters. Conditions in the steel industry are changing and the Steel Corporation will certainly meet at the proper time any important changes that occur. For several weeks, until recently, the corporation operated at about 92 per cent of capacity. In the past fortnight its operations have been sensibly declining, being now probably at about 85 per cent. Further decreases are to be expected. If the operation decreased to 60 per cent, the corporation management would undoubtedly consider the whole subject of prices and wages afresh and might then decide to reduce both.

The Steel Corporation's unfilled obligations decreased by 574,958 tons in January, this being 300,000 tons less than the December decrease. Shipments were slightly less, while actual bookings were hardly increased. A month ago it was commonly reported that toward the close of December the corporation went over its books and carefully cut out all doubtful tonnages, and apparently there were no cancellations of consequence in January. This would account for the divergence. Stated in estimated percentages of the corporation's capacity for a month, the matter may be put thus: December shipments, 94 per cent; unfilled tonnage decrease, 64 per cent; net bookings, 30 per cent, made up of actual bookings of 50 per cent and cancellations of 20 per cent; January shipments, 90 per cent; unfilled tonnage decrease, 44 per cent; bookings, 44 per cent.

PIG IRON PRICES

Foundry pig iron has declined another dollar a ton, to \$28 valley, on a rather small turnover. Bessemer and basic are unquotable. Regular producers state that they have had no occasion, on account of lack of inquiry, to depart from their former quotations of \$32 for bessemer and \$30 for basic, but would welcome the opportunity to do so. It is understood that some odd lots of basic could be picked up from steel interests that do not usually sell in the market at well under \$30. On account of the break in steel prices now in progress and the further decline in foundry iron, it is probable that producers will of their own accord announce new prices, which may be in the neighborhood of \$28.50 for bessemer and \$27 for basic. Such prices would probably represent a loss on the basis of recent costs, but efforts are being made to reduce costs and some of the Connellsville coke operators are anxious to co-operate in such work.

Production of steel ingots in January was at the rate of about 90 per cent of capacity by the Steel Corporation and 28 per cent by the independents. From the present outlook February production may be 80 or 85 per cent by the corporation and about 25 per cent by the independents.

Fusel oil, ref.....	gal.		3.50 - 3.60
Fusel oil, crude.....	gal.		2.75 - 3.00
Glauber's salt (see sodium sulphate).....	lb.		.20 - .21
Glycerine, C. P. drums extra.....	lb.		3.85 - 4.00
Iodine, resublimed.....	lb.		.10 - .20
Iron oxide, red.....	lb.		1.75 - 2.00
Iron sulphate (copperas).....	100 lb.	1.25 - 1.50	
Lead acetate, normal.....	lb.		.14 1/2 - .16
Lead arsenate (paste).....	lb.	.11 - .12	.12 1/2 - .13
Lead nitrate.....	lb.		.15 - .20
Litharge.....	lb.	.08 1/2 - .09	.09 1/2 - .10
Lithium carbonate.....	lb.		1.25 -
Magnesium carbonate, technical.....	lb.	.10 1/2 - .11	.11 1/2 - .12
Magnesium sulphate, U. S. P.....	100 lb.	2.50 - 3.00	
Magnesium sulphate, commercial.....	100 lb.		1.50 - 1.75
Methanol, 95%.....	gal.		1.28 - 1.30
Methanol, pure.....	gal.		1.60 - 1.65
Nickel salt, double.....	lb.		.12 - .12 1/2
Nickel salt, single.....	lb.		.13 - .13 1/2
Phosgene (see carbonyl chloride).....	lb.		
Phosphorus, red.....	lb.	.45 - .46	.47 - .50
Phosphorus, yellow.....	lb.		.35 - .37
Potassium bichromate.....	lb.	.14 1/2 - .14 1/2	.15 - .15 1/2

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$.35 — .40	\$0.30 — \$0.35
Potassium bromide, granular..... lb.	.35 — .40	.20 — .40
Potassium carbonate, U. S. P..... lb.	.08 — .08½	.45 — .50
Potassium carbonate, crude..... lb.	.08 — .10	.09 — .10
Potassium chlorate, crystals..... lb.	.14 — .14½	.11 — .18
Potassium cyanide..... lb.	.14 — .14½	.65 — .70
Potassium hydroxide (caustic potash)..... lb.	.14 — .14½	.15 — .16

Zinc chloride, gran..... lb.	.12 — .13	.13½ — .14
Zinc cyanide..... lb.	.08½ — .09	.09½ — .11
Zinc dust..... lb.	.03½ — .03¾	.04 — .06
Zinc oxide, XX..... lb.		
Zinc sulphate..... lb.		

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 — \$1.15
Alpha-naphthol, refined..... lb.	1.45 — 1.50
Alpha-naphthylamine..... lb.	.38 — .40
Aniline oil, drums extra..... lb.	.21 — .27
Aniline salts..... lb.	.27 — .30
Anthracene, 80% in drums (100 lb.)..... lb.	.75 — 1.00
Benzaldehyde U.S.P..... lb.	1.00 — 2.10
Benzidine, base..... lb.	1.00 — 1.10
Benzidine sulphate..... lb.	.80 — .90
Benzoic acid, U.S.P..... lb.	.70 — .75
Benzoate of soda, U.S.P..... lb.	.70 — .80
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)..... gal.	.28 — .32
Benzyl chloride, 95-97%, refined..... lb.	.30 — .35
Benzyl chloride, tech..... lb.	.25 — .30
Beta-naphthol benzoate..... lb.	3.50 — 4.00
Beta-naphthol, sublimed..... lb.	.70 — .75
Beta-naphthol, tech..... lb.	.30 — .35
Beta-naphthylamine, sublimed..... lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)..... lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums..... gal.	.95 — 1.00
Cresylic acid, 95-97%, dark, in drums..... gal.	.90 — .95
Cresylic acid, 50%, first quality, drums..... gal.	.60 — .65
Dichlorobenzene..... lb.	.06 — .09
Diethylaniline..... lb.	1.25 — 1.30
Dimethylaniline..... lb.	.55 — .65
Dinitrobenzene..... lb.	.30 — .32
Dinitrochlorobenzene..... lb.	.25 — .30
Dinitronaphthalene..... lb.	.33 — .35
Dinitrophenol..... lb.	.40 — .45
Dinitrotoluene..... lb.	.25 — .30
Dip oil, 25%, tar acids, car lots, in drums..... gal.	.37½ — .40
Diphenylamine..... lb.	.60 — .70
H-acid..... lb.	1.30 — 1.50
Meta-phenylenediamine..... lb.	1.25 — 1.30
Monochlorobenzene..... lb.	.14 — .16
Monoethylaniline..... lb.	1.80 — 2.00
Naphthalene crushed, in bbls. (250 lb.)..... lb.	.07½ — .08
Naphthalene, flake..... lb.	.08 — .08½
Naphthalene, balls..... lb.	.08 — .08½
Naphthionic acid, crude..... lb.	.70 — .75
Nitrobenzene..... lb.	.12 — .15
Nitro-naphthalene..... lb.	.30 — .35
Nitro-toluene..... lb.	.18 — .25
Ortho-amidophenol..... lb.	3.20 — 3.75
Ortho-dichlor-benzene..... lb.	.15 — .20
Ortho-nitro-phenol..... lb.	.75 — .80
Ortho-nitro-toluene..... lb.	.20 — .24
Ortho-toluidine..... lb.	.25 — .30
Para-amidophenol, base..... lb.	1.90 — 2.00
Para-amidophenol, HCl..... lb.	2.10 — 2.20

Para-dichlorobenzene..... lb.	.15 — .25
Paranitroaniline..... lb.	.85 — .90
Para-nitrotoluene..... lb.	.90 — 1.05
Para-phenylenediamine..... lb.	1.80 — 2.20
Para-toluidine..... lb.	1.30 — 1.60
Phthalic anhydride..... lb.	.55 — .60
Phenol, U. S. P., drums (dest.), (240 lb.)..... lb.	.10 — .12
Pyridine..... gal.	2.00 — 3.50
Resorcinol, technical..... lb.	1.85 — 2.00
Resorcinol, pure..... lb.	2.50 — 2.75
Salicylic acid, tech., in bbls. (110 lb.)..... lb.	.23 — .25
Salicylic acid, U. S. P..... lb.	.27 — .30
Salol..... lb.	.85 — .95
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.28 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.16 — .18
Sulphanilic acid, crude..... lb.	.30 — .35
Tolidine..... lb.	1.35 — 1.45
Toluidine, mixed..... lb.	.40 — .45
Toluene, in tank cars..... gal.	.28 — .32
Toluene, in drums..... gal.	.30 — .35
Xylidines, drums, 100 gal..... lb.	.40 — .45
Xylene, pure, in drums..... gal.	.42 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 — \$0.26
Beeswax, refined, light..... lb.	.27 — .28
Beeswax, white pure..... lb.	.40 — .45
Carnauba, No. 1..... lb.	.75 — .77
Carnauba, No. 2, North Country..... lb.	.33 — .35
Carnauba, No. 3, North Country..... lb.	.18 — .19
Japan..... lb.	.19 — .20
Montan, crude..... lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04½ — .04¾
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.04 — .04½
Paraffine waxes, refined, 118-120 m.p..... lb.	.05 — .05½
Paraffine waxes, refined, 125 m.p..... lb.	.06 — .06½
Paraffine waxes, refined, 128-130 m.p..... lb.	.06 — .06½
Paraffine waxes, refined, 133-135 m.p..... lb.	.07 — .07½
Paraffine waxes, refined, 135-137 m.p..... lb.	.09 — .09½
Stearic acid, single pressed..... lb.	.12 — .13
Stearic acid, double pressed..... lb.	.13 — .14
Stearic acid, triple pressed..... lb.	.14 — .15

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940..... gal.	\$1.70
Pine oil, pure, dest. dist..... gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr., 1.080-1.060..... gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.37
Pinewood creosote, ref..... gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl..... 280 lb.	\$8.00 —
Rosin E-I..... 280 lb.	8.00 —
Rosin K-N..... 280 lb.	8.00 —
Rosin W. G.-W. W..... 280 lb.	8.25 —
Wood rosin, bbl..... 280 lb.	8.50 —
Spirits of turpentine..... gal.	.60 —
Wood turpentine, steam dist..... gal.	.58 —
Wood turpentine, dest. dist..... gal.	.57 —
Pine tar pitch, bbl..... 200 lb.	8.50 —
Tar, kiln burned, bbl. (500 lb.)..... bbl.	15.00 — 15.00
Retort tar, bbl..... 500 lb.	15.00 — 15.50
Rosin oil, first run..... gal.	.50 —
Rosin oil, second run..... gal.	.52 —
Rosin oil, third run..... gal.	.60 —

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0.18½ — \$0.19
Upriver coarse..... lb.	.14 — .14½
Upriver caucho ball..... lb.	.14½ — .14¾
Plantation—First latex crepe..... lb.	.19½ — .19¾
Ribbed smoked sheets..... lb.	.18 — .18½
Brown crepe, thin, clean..... lb.	.18 — .18½
Amber crepe No. 1..... lb.	.20 — .20½

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.09½ — \$0.10
Castor oil, AA, in bbls..... lb.	.11 — .11½
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.08½ — .08¾
Cocoonut oil, Ceylon grade, in bbls..... lb.	.11½ — .12½
Cocoonut oil, Cochin grade, in bbls..... lb.	.12½ — .12¾
Cor. oil, crude, in bbls..... lb.	.08½ — .09
Cottonseed oil, crude (f. o. b. mill)..... lb.	.05 — .06
Cottonseed oil, summer yellow..... lb.	.08½ — .08¾
Cottonseed oil, winter yellow..... lb.	.09 — .09½
Linseed oil, raw, car lots (domestic)..... gal.	.68 — .69
Linseed oil, raw, tank cars (domestic)..... gal.	.61 — .61½
Linseed oil, boiled, car lots (domestic)..... gal.	.70 — .71

Olive oil, commercial.....	gal.	\$2.00	—	\$2.40
Palm, Lagos.....	lb.	.07½	—	.07½
Palm, Niger.....	lb.	.07	—	.07½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.06½	—	.07
Peanut oil, refined, in bbls.....	lb.	.13	—	.13½
Rapeseed oil, refined in bbls.....	gal.	1.10	—	1.15
Rapeseed oil, blown, in bbls.....	gal.	1.20	—	1.25
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.08	—	.08½
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.05	—	

FISH

Light pressed menhaden.....	gal.	\$0.46	—	\$0.48
Yellow bleached menhaden.....	gal.	.48	—	.50
White bleached menhaden.....	gal.	.50	—	.52
Blown menhaden.....	gal.	.85	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	17.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—

Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04½	—	.05
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (kaolin), imported, lump.....	net ton	23.00	—	25.00
China clay (kaolin), imported, powdered.....	net ton	30.00	—	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Fla.....	net ton	25.00	—	
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.....	lb.		—	.09
Graphite, crucible, 85% carbon, Ashland, Ala.....	lb.	.07	—	.09
Graphite, higher lubricating grades.....	lb.	.11	—	.40
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic lump.....	lb.	.05	—	.05½
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.65	—	
Shellac, orange superfine.....	lb.	.70	—	
Shellac, A. C. garnet.....	lb.	.57	—	
Shellac, T. N.....	lb.	.55	—	
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton		—	17.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	40.00	—	50.00
Talc, California talcum powder grade.....	ton	20.00	—	45.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	160	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	80-100	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	45-50	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton		55
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	55-60	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	45-50	
Magnesite brick, 9-in. straight.....	net ton	100	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	105	
Magnesite brick, soaps and splits.....	net ton	120	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	65-70	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	56-61	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,300	50-60	

Ferro-Alloys

All f.o.b. Works

Ferrocen-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrocen-titanium per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.16	—	
Ferrocen-titanium per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.16	—	.17
Ferromanganese, 76-80% Mn, domestic.....	gross ton	95.00	—	100.00
Ferromanganese, 76-80% Mn, English.....	gross ton	95.00	—	100.00
Spiegeleisen, 18-22% Mn.....	gross ton	38.00	—	40.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.00	—	2.50
Ferrosilicon, 10-15%.....	gross ton	50.00	—	55.00
Ferrosilicon, 50%.....	gross ton	78.00	—	80.00
Ferrosilicon, 75%.....	gross ton	140.00	—	145.00
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.55	—	.60
Ferrourenium, 35-50% of U, per lb. of U content.....	lb.	7.00	—	
Ferrovandium, 30-40% per lb. of contained V.....	lb.	5.00	—	5.25

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content, less than 2% Fe ₂ O ₃ , up to 20% silica, not more than H 4% moisture.....	gross ton	\$10.00	—	\$11.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Amer. Cement Tile Mfg. Co., 509 Brown Marx Bldg., had plans prepared for the construction of a 60-200-ft. plant. L. W. Barner, Southern mgr.

BIRMINGHAM—J. E. Brow, comn., had plans prepared for the construction of a 1-story bath house and water-sterilizing plant on Ave. I and 29th St. Estimated cost, \$45,000. J. Kendrick, Birmingham, engr.

California

STOCKTON—A. L. Banks, city clk., receives bids until March 8 for the construction of the south sewage disposal works, including chlorination equipment, settling tank, sludge beds, etc. W. B. Hogan, city engr.

Illinois

CHICAGO—W. G. Uffendel, archt., 39 South State St., will soon award contract for the construction of a 2-story, 116x118-ft. engraving factory on Fullerton and Racine Aves., for J. B. Wiggins, 1104 South Wabash Ave. Estimated cost, \$75,000.

Iowa

DUBUQUE—The Bd. Educ. is having plans prepared for the construction of a 3-story high school. A chemical laboratory will be installed in same. Estimated cost, \$550,000. J. W. Royer, Urbana, Ill., archt.

GILMAN—The Bd. Educ. receives bids March 4 for the construction of a 2-story, 60x100-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$110,000. Keffer & Jones, 204 Masonic Temple, Des Moines, archts.

SHELLSBURG—The Bd. Educ. receives bids until March 11 for the construction of a 3-story, 80x110-ft. grade and high school. A chemical laboratory will be installed in same. Estimated cost, \$140,000. A. K. Rife, secy. J. G. Ralston, 709 L. & J. Bldg., Waterloo, archt. Noted Nov. 17.

Michigan

PLAINWELL—The Bd. Educ. is having plans prepared for the construction of a 2-story, 100x196-ft. high school. A chemical laboratory will be installed in same. About \$175,000. E. S. Batteson, Kalamazoo, archt.

Minnesota

CLOQUET—R. C. Hornby and R. M. Weyerhaeuser, representing owner, plan the construction of a mill to manufacture wall-board from saw mill waste near the Northern Lumber Co. Estimated cost, \$250,000.

HACKENSACK—Bd. Educ., c/o F. R. Ross, Walker, receives bids until March 4 for the construction of a 2-story, 95x102-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$75,000. Liebenberg, Kaplan & Martin, 615 McKnight Bldg., Minneapolis, archts. Noted Dec. 29.

Missouri

COLUMBIA—City plans to construct sewage disposal plant, Imhoff tanks and sprinkling filters. Estimated cost, \$177,000.

ST. LOUIS—L. Haeger, archt., 3844 Utah Pl., will soon award contract for the construction of a 1-story, 50x100-ft. foundry, for The Chester Iron & Fdry. Co., 7000 Vulcan St. Estimated cost, \$30,000. E. A. Linnis, secy.

New Jersey

NEWARK—Barrison & Blase, South St., receives bids Feb. 21 for the construction of a 2-story brick and concrete factory on Governor St. and Marion Pl. About \$75,000. F. Grad, 245 Springfield Ave., engr.

New York

BROOKLYN—Burley Welding Works, 22 Kosciuszko St., will build a 3-story addition

to its factory. Estimated cost, \$50,000. E. M. Adelshon, 1778 Pitkin Ave., engr.

VICTOR—The Victor Plaster Co., recently incorporated to mine gypsum, plans to expend \$140,000 for buildings and equipment. C. A. Huber, 51 Monroe Ave., Rochester, pres.

Ohio

CLEVELAND—Electric Steel & Forge Co., c/o J. H. Foster, pres., 6600 Grant Ave., plans to construct a 1-story steel rolling mill. Estimated cost, \$200,000. J. H. Heron & Co., 1360 West 3d St., archts. and engr.

COLUMBUS—The Ironclay Brick Co., 64 Ruggery Bldg., has awarded the contract for the construction of a 1-story, 60x175-ft. factory on East 2nd Ave. Estimated cost, \$45,000.

WARREN—City has awarded the contract for the construction of a 6,000,000 gal. per day addition to present filtration plant. Estimated cost, \$210,000.

South Dakota

GROTON—The Bd. Educ., School Dist. 33, is having plans prepared for the construction of a 2-story, 118x147-ft. high and grade school. A chemical laboratory will be installed in same. Estimated cost, \$200,000. E. Krueger, pres. E. F. Broomhall, 710 Alworth Bldg., Duluth, Minn., archt.

RAMONA—The Bd. Educ. is having plans prepared for the construction of a 2-story, rein.-con., brick and tile high school. A chemical laboratory will be installed in same. Estimated cost, \$150,000.

WATERTOWN—The Bd. Educ. is having plans prepared for the construction of a 3-story, 152-178-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$250,000. M. Herzel, clk. Tyrie & Chapman, archts. and C. L. Pillsbury Co., engr., 1206 Second Ave., S., Minneapolis, Minn. Noted Dec. 22.

Vermont

WINDSOR—The Windsor Fdry. Co. had plans prepared for the construction of a 1-story, 115x252-ft. foundry. Waldron & Van Winckle, 37 Wall St., New York City, archts. and engr. Noted Dec. 29.

West Virginia

ST. ALBANS—The St. Albans Light & Power Co., Charleston, plans to construct a filtration plant here. Estimated cost, \$75,000. A. Campbell, gen. mgr.

Wisconsin

ST. CROIX FALLS—Bd. Educ. will receive b'ds in the spring for the construction of a 2-story, 53x90-ft. high school. A chemical laboratory will be installed in same. Estimated cost, \$85,000. J. B. Stevenson, clk. W. L. Albam, 347 Endicott Bldg., St. Paul, Minn., archt. Terry & Schulte Engr. Co., 486 Endicott Bldg., St. Paul, engr.

Ontario

LONDON—E. V. Buchanan, engr. Pub. Utilities Comm., Hydro Bldg., plans the construction of a deferrization plant in connection with the water-works system and is in the market for deferrization equipment.

LONDON—Utilities Bd. has awarded the contract for the construction of a filtration plant to remove iron from the water to Permutit Co., 440 Fourth Ave., New York City. Estimated cost, \$40,000.

Quebec

DELSON—The Delson Brick Co., Montreal, will construct a plant here and install equipment.

MONTREAL—F. L. Ross, 7 York Lane, Cote St. Paul, plans to construct a 1-story brick and steel plant for the making of sirup. Estimated cost, \$25,000.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY will hold its annual meeting Feb. 21 to 24 at Columbus, Ohio, with headquarters at the Deschler Hotel.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS is holding its spring meeting Feb. 14 to 17 in New York City.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 and 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Manufacturers' Catalogs

ACHESON GRAPHITE Co., Niagara Falls, N. Y., is distributing its new catalog on "Acheson Electrodes in Use." It contains photographs of a few of the furnaces in operation, which were chosen as each is typical of the class it represents and the kind of work it is doing. In reference to the pictures of brass furnaces only the arc type or those using electrodes are shown. There are also brass furnaces using Acheson resistor for the heating element.

THE FOAMITE FIREFOAM Co., New York City, is now issuing a monthly magazine called *Industrial Fire Chief*, which is devoted to the advancement of fire-protection engineering. The issue for January, 1921, is vol. 1, No. 4. Well-illustrated articles are included, together with a section on "The Day's Mail," which comprise letters from users of the company's product.

RUGGLES-COLES ENGINEERING Co., New York City, calls attention to Catalog 16, which describes the various types of driers. This company has designed eight distinct types of drying machines, which cover the field of drying as completely as possible. Each type is described and the use to which it may be put, together with illustrations of them.

PITTSBURGH INSTRUMENT & MACHINE Co. has just issued a pamphlet on a continuous and alternating impact testing machine to be used in connection with the testing of airplane, automobile and other machine parts which are exposed to shock.

An Important Position Filled

IN THE selection of LAWRENCE WILKERSON WALLACE as executive secretary of American Engineering Council we believe that a wise choice has been made and that the purposes and objects of Council will be forwarded and accomplished promptly and efficiently. A casual survey of Mr. WALLACE'S training and experience together with a knowledge of his personal characteristics and leanings lead us to believe that in him Council has a fitting team mate for Mr. HOOVER. Trained as a mechanical engineer, experienced not only in the practice of his profession but also in the instruction of those who have selected it as their life work, Mr. WALLACE brings to the secretaryship those precise habits of thought and action which mark the engineering executive. But more than this, he brings a genuine sympathetic interest in the human element in industry which gives him a point of view particularly needed in Council's first great work—a survey of industrial wastes. His address on Conservation of Labor, at the meeting of Council in Washington last fall, was one of the high lights of the convention. His broad interest in engineering is indicated by the fact that he has been three times chosen president of the Society of Industrial Engineers.

Mr. WALLACE has been elected to one of the most important and exacting positions in engineering societies, but we feel confident that he will be found active and capable and that American Engineering Council will be able to point to a definite record of achievement under his secretaryship.

Inadequate Support of Foreign Trade Representatives

THE United States today is practically in the position of a business man with many bills receivable who declines to provide collectors to go out and arrange for the settlement of the obligations due him. Foreign nations owe the United States several billion dollars, an important fact which we can all well appreciate when we come to pay our income taxes. The most promising method of securing return for these loans is through the channels of international trade, both with the nations to which the loans were made and with others which are indirectly able to facilitate payment of the loans. The foreign representatives of this Government who are required as one link in our business chain are the foreign trade representatives in the Bureau of Foreign and Domestic Commerce and in the consular service of the State Department. It is of great importance, therefore, that American indus-

try consider how these representatives of American business are to be provided for during the coming year.

According to the House of Representatives' proposals the Bureau of Foreign and Domestic Commerce will have approximately \$900,000 to conduct its affairs during the next fiscal year, an amount equal to less than one-fiftieth of one per cent of the total Government expenditures. This is only 60 per cent of the minimum sum which the Secretary of Commerce believes to be necessary for effective conduct of trade matters. Fortunately the Senate Committee on Appropriations was a little more generously disposed and suggested an increase of \$50,000 in these funds. Certainly it is to be hoped that the larger amount will be provided, though even it is far too small for full attention to this important foreign trade activity.

The Consular Service and the other branches of the State Department dealing with trade matters were provided for most inadequately in the House of Representatives. The appropriation suggested for them was nearly a million dollars less than during the present year. The Senate, however, again comes to the rescue and has by committee action increased the provision for this service to a more nearly adequate sum. In conference this difference between the two houses of Congress will have to be adjusted and here again the far-seeing business men of the country will certainly wish that the larger appropriation be granted, even though it may seem to be an increase in the burden of taxation. As a matter of fact, it is the most far-seeing investment in foreign trade which our Congress can provide.

In dealing with all these matters one must remember that the transfer of money for the payment of international indebtedness is now, even more than formerly, a matter of practical impossibility. Our debtors can repay us only with raw materials or manufactured goods. If we keep in touch with their markets and production conditions we can most effectively learn what and where to buy as well as what and where to sell.

Those nations to which we sell largely will generally be those that are not indebted to us, but rather those from which we draw many of our most important raw materials. Cultivation of friendship and active trade relation with them obviously is as much an advantage as with those from which we desire to secure something in compensation for funds previously loaned. In other words, no matter what nation we consider, it is worth while to have adequate commercial investigators and consular representatives on foreign ground for the advice of American industry.

Iron and Steel Production Costs

ALREADY not a few iron and steel manufacturers have begun to express regret at the course the iron and steel market was permitted to pursue in 1920, when prices advanced sharply partly through competitive bidding by consumers, particularly automobile and parts makers, and partly through producers definitely seeking the highest obtainable prices.

It is being found now that the net results of operations at high prices were not as satisfactory as they appeared to be at the time. There are two chief flaws, one being that the manufacturers do not today find themselves in possession of all the profits they thought they were making, the other being that they do find themselves with very high production costs.

With many manufacturers it was a case of "come easy, go easy." There was no difficulty in obtaining high prices, for buyers came to the plants and bid advanced prices to secure material, but when the pressure was for material and receipts were large altogether unbusinesslike expedients were resorted to with the object of maintaining or increasing production. While the customers of independent steel mills were competing with one another to get steel, for instance, some of the steel makers were competing with one another to get Connellsville coke, with the result that for weeks the market for spot Connellsville coke averaged about \$18 per net ton at ovens, when in May, 1915, the same coke, only much better quality, had sold at \$1.50. Labor was scarce and knew it, so bonuses were paid and men were practically bribed to stay on the payroll.

During the period of inflated prices in steel there was criticism of the mills in some quarters on the ground that the market was "riding for a fall." The probability is that the manufacturers realized that a break was going to come, but reasoned that a break would occur in any event and would be no more damaging if from one height than if from another. That seemed to be fairly good logic had it not been for the constantly mounting costs.

In striking contrast with the course of the independents in 1920 was the course of the United States Steel Corporation, which kept its prices at the Industrial Board schedule of March 21, 1919, and refrained from attempting to swell its production by unusual or competitive methods. The corporation was very short of coke, but made no effort to buy in the open market. It could not furnish all the steel its customers desired, but it refused to let them bid against one another. Thus the corporation has built up its good will. The corporation has high costs, relative to those in the past, but it has not a great deal to liquidate except by a general wage reduction, which will eventually be made.

A difficulty confronting the independent steel producers at this time is that while they are anxious to reduce their costs and get down to a really economical basis it is impossible to reduce costs when there is no operation. At the moment there is not enough business to be had to operate upon, except in a way that would make no real showing as to costs.

The task before the steel industry is, however, a stupendous one. In the years just before the war there was question whether the productive capacity was not somewhat greater than was really needed, for the spells of light operation had been almost as long as the spells

of full operation. There was no calendar year of full operation throughout, after 1906, until the war demand produced full operation in 1916. Nevertheless pig iron capacity is 35 to 40 per cent greater than in 1914 and steel making capacity about 50 per cent greater. It is necessary therefore to produce with the greatest possible economy in order to build up a demand that will employ the capacity.

Decentralization in Technical Societies

IN HIS address last week as retiring president of the American Institute of Mining and Metallurgical Engineers Mr. HOOVER reviewed the Institute's important activities during the year 1920. Among the most important of these he regarded the trend toward decentralization as offering the greatest promise for the welfare and influence of the Institute as a whole. The increase in the number of local sections and their growth as important factors in the life of the Institute he regarded as one of the outstanding achievements of his administration and he commended to his successor in office the adoption of a policy that would foster this tendency.

It is worth recording here that the Mining Engineers are not alone in this decided drift toward enhancing the importance of the local section and decentralizing Institute activities. The other great national engineering societies have been showing this drift in more or less marked degree. The Mechanical Engineers have for some time past recognized the importance of fostering local sections and encouraging them to greater activity and participation in society affairs. The Electrical Engineers also, we believe, have a form of government which results in as much decentralization as is consistent with the conduct of the Institute's business at headquarters. The recent complete change in régime in the Civil Engineers was the consequence of dissatisfaction with highly centralized authority, and a determination to recognize the increasing importance of local sections. And finally it may be noted that the administration of the newly organized Federated American Engineering Societies is convinced that this great body can function to best advantage through the activities of state sections or groups.

Apparently enlightened opinion on the conduct of technical societies has recognized the evils of a highly centralized organization, with its tendency to dominate affairs through a self-perpetuated clique that fears to let the membership get out of hand through too great local activity. It is, of course, recognized that in all national societies there must be enough officers and directors living near headquarters to insure the transaction of regular business, but beyond that there should be no attempt to limit or control the activities of the membership through fear that the local section might grow in power and menace the solidarity of the parent organization. Rather should local sections be encouraged to increase their strength and influence by joining with other local, state and regional societies for participation in local public affairs. Affiliation with Chambers of Commerce and co-operation with representatives of the local government will be found to be fruitful fields of endeavor. From these activities the local bodies will acquire a lively sense of importance, to which the prestige of their national organizations will make a further contribution. With a number of

such flourishing local organizations receiving encouragement and support from headquarters the reaction on the parent organization can have but a beneficial and desirable effect. The day is past when a local section of any national technical society can be a nonentity without contributing toward centralization of authority and rule by clique.

Improvement

In Drill Steels

IT APPEARS from figures presented by B. F. TILLSON before the recent meeting of the American Institute of Mining and Metallurgical Engineers that a perfectly amazing number of breakages in drill steel is accepted as a matter of course by men in charge of rock-drilling operations. Mechanical sharpeners, drilling machines and details of drill bit and shank have been perfected with infinite care, yet one out of every hundred pieces of drill steel tightened in a chuck breaks short across in the shaft before becoming dull. Records for heavy drills have shown a loss from breakage as high as 7 per cent per shift. This involves a waste which is surely worthy of attention.

Disregarding the influence of rough handling underground, and improper operation of the drilling machine, which are evidently matters for the attention of the mining men, the responsibility for this great mortality in drill steel may rest primarily in the stresses imposed in service, in the composition or constitution of the steel itself, or in its heat-treatment during and after forging the shank or bit ("sharpening").

Drill breakage is mostly confined to the shaft of the drill itself. If a portion of the bit flakes off, the drill is ordinarily classed as "dull," and is reforged. Transverse breaks in the drill rod itself, which are the cause of the present inquiry, are often ascribed to the progressive extension of "fatigue checks," such fractures having been induced in test runs after 50,000 impacts. However, it is difficult to see how so few alternations could cause the damage in view of Prof. MOORE'S work at Urbana showing that 100 million alternations at the elastic limit were insufficient to rupture either ingot iron or normalized eutectoid steel, unless the beating of the drill bit against the rock is so timed with the vibrations along the drill shaft as to build up standing waves of high amplitude, or unless the steel is dirty or highly segregated. Hot spots along the length of a drill when in use are ascribed to such stress waves, and their importance was experimentally shown by Dr. BURROWS. Since records at the New Jersey Zinc Co. undoubtedly showed that if a broken drill be resharpened, a second break will occur after a shorter time in service than the first, and a still shorter time after each succeeding repair, Mr. TILLSON argued that fatigue was responsible, but the same facts would result from the cumulative damage done by successive improper forgings and heat-treatments.

But the steel itself may be faulty. The work it must do is most severe. It is continually in the hands of workmen of more brawn than brains throughout its journey from steel plant as drill rod back to the steel plant as scrap. Perhaps it is unfair to expect one rod of uniform composition to be able to be so hard at its point that it will bite into granite, and yet tough enough along the shaft to transmit the impact of heavy driving piston, and at the same time withstand occasional sledge blows from sweating miners.

Many of the breaks exhibit the detail fracture characteristic of transverse fissures in rails, about which so much has been said and so little is known. If these fractures can be readily induced in drill rods, their study may easily throw a great deal of light on sound steel for rails. Undoubtedly segregation at the nucleus has much to do with starting these failures. Segregation occurs every time a steel ingot solidifies and will to the end of time. Some of it can be later removed by correct heat-treatment, but solid non-metallic inclusions—a perfectly normal constituent of steel—remain more or less unaffected. A thorough research into drill steel will have to determine what sonims are harmful and what sonims are harmless.

Those who have watched the mine blacksmith at work, or even observed the elaborate drill-sharpening plant of the Calumet & Hecla company, controlled as it is by the human eye pyrometer, are not surprised at Mr. FOLEY'S analysis showing by far the largest proportion of breakages to occur near ends—where the cold steel rod was heated preparatory to forging, but where it received no working; where it acquired a coarsely crystalline structure and was cooled slowly, receiving no subsequent grain refinement. Undoubtedly these failures were due to faulty heat-treatment, yet if education of the smiths can progress so that the more glaring abuses are prevented it is difficult to see how the remaining failures can be improved short of a complex heat-treatment of the end, or a more simple heat-treatment of the entire rod, either of which is beyond the skill and resources of any but the largest and most progressive mining companies.

Meanwhile cannot metallurgists offer a different kind of steel which is more nearly fool-proof than the plain high-carbon hollow hexagons now so largely bought and broken? An indication that the composition is not beyond improvement is the fact that rods made up of electrically butt welded pieces very seldom break at the welds, where undoubtedly a considerable amount of decarbonized metal exists. If a carburized bit and decarburized shaft is impracticable, cannot alloy steels be substituted for the carbon steels, admittedly less responsive and more "tricky" or tender under heat-treatment than many more complex compositions? It is known that the steel which acquires the full measure of its possibilities after the fewest and least drastic heat-treatments is of such a nature that the transformation starts at locations which are packed closest together. It is also known that a steel exhibiting high thermal hysteresis will acquire similar physical properties despite rather large variations in the quenching and annealing temperatures. Many alloy steels have closely packed crystallization and transformation centers and at the same time a considerable temperature interval between the critical points. Have these steels not been exploited? is the price too high? or are mining men too timid to attempt reforming the blacksmith shop?

Whatever the answer to these queries, we welcome the co-operative investigation of drill steel. The questions raised by a preliminary survey of the problem by mining engineers (not metallurgists) are precisely those which are fundamental to the modern science of physical metallurgy. If investigators in pure science needed justification, they could point to this new inquiry of a distinctly "practical" nature to prove the commercial utility of a study into Fe:C:O equilibrium, the chemical composition of emulsified inclusions, or atomic configuration in metallic crystals.

Notes on French Industries

FROM OUR PARIS CORRESPONDENT

PARIS, Jan. 15, 1921.

THE condition of the French chemical and metallurgical industries at the beginning of 1921 is far from satisfactory. Plants erected during and subsequent to the war have enjoyed a short period of prosperity, but now that German products are again on the French market the competition with home products is strong and greatly in favor of the Germans. The young industries did not develop the vitality necessary to enable them to meet with immunity the present economic difficulties.

STATUS OF THE CHEMICAL INDUSTRIES

The crisis is most pronounced in the synthetic dye industry. During the last few years France made great efforts to develop this industry to a point where she could make 765 metric tons per month (August, 1920), but at present the production is steadily declining, as shown by the figures for September and October—640 and 625 tons respectively. The official figures for the last two months of 1920 undoubtedly will show an even more marked decline. The total production of dyes is hardly sufficient to supply 50 per cent of the total French consumption, which is now about 12,000 tons per year.

During 1920 the Germans supplied 2,255 tons at a cost of 32 million marks, of which 1,275 tons, valued at 19.5 million marks was delivered between May and the end of December, 1920.

The present French tariff on dye importations is of practically no help to the French industry because the import duty is negligible when it is considered that the price of dyes has increased up to tenfold and more.

One of the few successful new chemical companies, the Société Alsacienne de Produits Chimiques, which is in reality the successor to the Société de Produits Chimiques de Thann et Mulhouse, has increased its capital from 16 to 30 million francs and has consolidated with the Société des Produits Chimiques de La Rochelle. The company is now erecting a synthetic camphor plant at La Rochelle. It is worth mentioning that the erection of this plant was decided upon when camphor sold at 85 f. per kg. and that now camphor is quoted at 40 f. per kg. The officials of the company state, however, that the drop in price will not affect them, as they have contracts for the sale of their total production at the former price, and that in addition the cost of the principal raw material (essence of turpentine) has dropped from 1,000 f. to 580 f. per 100 kg.

THE STATUS OF THE METALLURGICAL INDUSTRY

The most optimistic comment that can be made concerning the French metallurgical industries is that better days are expected in the near future. The government hopes to have helped the iron industry somewhat by fixing the price of blast-furnace coke at 135 f. per ton beginning Jan. 1, 1921, which means an abrupt reduction of 40 f. per ton, the price for coke used in all other industries being fixed at 200 f. per ton.

The metallurgical industries of Lorraine suffer the most due to the fact that the sale of the Lorraine plants to French firms after peace was declared took place under very abnormal conditions. The buyers' bids were not based on the actual value of the production capacity of the plants but on the desire to acquire them at any price. The result is that there are now in Lorraine a

number of overcapitalized enterprises of a producing capacity far over the present market demands and which are forced continuously to lower the selling price of their products to meet their most pressing financial needs. The consequence of this abnormal situation is that a number of Lorraine plants and practically all the plants in the Department of Meurthe and Moselle are shut down, a condition without precedent in the history of the French metallurgical industry. It is stated that the producers in the above two departments have about 200,000 tons of pig iron in stock and are anxiously waiting for buyers. What makes the condition even worse is the strong competition of the Germans who take advantage of the abnormal exchange rate of the mark and who again make efficient use of their former dumping policy.

SOYA OIL COMPETING WITH ARACHIS OIL IN THE SOAP INDUSTRY

The Marseilles soap industry is now using great quantities of hardened arachis oil (peanut oil) supplied exclusively by England. The advantages of using the hardened product are an economy of 35 per cent over the use of industrial arachis oil and a harder soap. Encouraged by these results, the Marseilles manufacturers, wishing to become independent of the English supply of this important product, are trying to induce the French producers of arachis oil in West Africa to install their own plants for the hardening of the oil. The hardened oil now sells in Marseilles at 360 f. per 100 kg. The use of soya oil gives results similar to those obtained with hardened arachis oil and Japan is now trying to introduce the use of soya oil by offering it at 340 f. per 100 kg. A strong competition is now going on as to which product shall prevail in the soap industry.

PROGRESS OF THE FRENCH POWDER AND EXPLOSIVES INDUSTRIES

Prof. Haller has recently presented two papers before the Société d'Encouragement pour l'Industrie Nationale de France on the work of French chemists in the powder and explosives industries during the war. The following few figures he mentioned may give an idea of the rapid progress realized.

B-powder (nitrocellulose). The production in August, 1914, was 14 tons per day; in 1917 it reached 367 tons per day.

Nitrated Explosives. The production in August, 1914, was 8 to 9 tons per day; in July, 1917, it reached 700 tons per day.

In 1917 France produced 175 tons per day of chlorated explosives, which were used mostly in the preparation of grenades.

American Chamber of Commerce in France

At the annual meeting of the American Chamber of Commerce in France held in Paris, Jan. 17, 1921, A. M. Thackara, American Consul-General in Paris, spoke on France's export to the United States during 1920. The grand total value of the French export to continental United States and its possessions amounted to \$467,158,848, as compared with \$168,146,032 in 1919.

There are now 978 members, as against 800 in 1919 and 473 in 1918. The officers for 1921 are: Walter V. R. Berry, president; Charles E. Carpenter and A. D. Veil, vice-presidents; W. Morgan Day, treasurer, and V. K. Stevenson, honorary secretary.

American Institute of Mining and Metallurgical Engineers

Abstracts of Papers Presented Before the Winter Meeting, With Notes on the Technical Discussions—
Notable Sessions on Ferrous and Non-Ferrous Metallurgy, Including an Excellent Symposium on
Breakage and Heat-Treatment of Drill Steel

NEW YORK entertained, in the usual manner, the winter meeting of the American Institute of Mining and Metallurgical Engineers, Feb. 14 to 17. Fifty or more papers were presented at fourteen technical sessions, many excellent ones being read from author's manuscript, owing to the fact that the Institute's funds are apparently not large enough to cover the cost of pre-printing them. This results in perhaps more attention to the paper on the part of the members present at the technical sessions, but prevents the attention and profit of the nine thousand or more less fortunate members. Furthermore, some of the metallurgical papers were held over from the Lake Superior meeting, possibly for geographical reasons. Two long sessions, under the able chairmanship of B. F. Tillson, presented a symposium on failures in drill steel, reference to which is made editorially in this issue.

Physical conditions surrounding the meeting were rather better than the average. Programs were carried through promptly and without delays, entertainment features on the whole were quite good, and were enjoyed by members of all ages and their guests. The Institute will perhaps never again be so fortunate as to have Herbert Hoover for president and E. P. Mathewson for host at the same meeting. Edwin Ludlow, the new president, assumed the duties of his office at the closing banquet.

Non-Ferrous Metallurgy

A. B. Young, superintendent of the Tooele Plant, International Smelting Co., described the flue-type treater handling the company's roaster gases, an installation whose details have already been given in *CHEMICAL & METALLURGICAL ENGINEERING* for Dec. 29, 1920, vol. 23, p. 1244. It excited favorable comment as to its economy in first cost and operating charges. It is there used primarily to catch true dust. A. A. Heimrod cited two other installations of this type, of the same size, one precipitating dust whereas the other cleared fume. The latter required about four times the power input.

ELECTROLYTIC ZINC

The paper by Frederick Laist and his associates on Anaconda's Electrolytic Zinc Plant has already been reviewed at length in the columns of this journal (Feb. 9, 1921, vol. 24, p. 245), but the original paper, with its enormous amount of data, should be in the hands of all men interested in this phase of metallurgy. Discussion brought out a very interesting contrast in views. S. C. Bullock, writing from England, emphasized the need of extreme purity in tank solutions, while W. C. Smith described informally the process in operation at Martinez, Cal., developed by Messrs. Tainton and Pring. Using Australasian ore, Mr. Bullock finds that a most elaborate purification cycle is necessary. Nickel and cobalt especially must

be eliminated to less than 0.0001 per cent—in fact nickel was ordinarily kept about 0.00002 per cent; such special efforts were found to pay in a gratifying increase in tank efficiency. Hand-rabbed furnaces were favored in Great Britain. Conversion of 97 per cent zinc to soluble form was not rare, while 90 per cent soluble was regarded as merely fair practice on very difficult Australian ore. Iron was ordinarily removed after filtration; it was removed by aëration and CaCO_3 .

At Martinez the calcines are ordinarily separated magnetically into two portions. The first, or magnetic (iron), portion leached with hot strong acid—27 per cent H_2SO_4 —the spent cell solution. When the free acid has been reduced about one-half, further neutralization is effected by the second or oxidized portion of the calcine. The resulting solution contains as high as 200 g. Zn per liter, and of course must be filtered hot. The purification cycle is relatively simple, but is effected by an unrevealed method; the purification, however, is not nearly as high as otherwise. Cobalt or arsenic can run as high as 30 mg. per liter; antimony, however, is much more troublesome. Clear solution is added to the circulation to keep the heads at about 70 g. Zn per liter. It is electrolyzed until about 30 g. remain, using a very high current density—100 amp. per sq.ft. Electrode spacing is $1\frac{3}{8}$ -in. face to face; voltage is about 4 volts per cell. It is evidently necessary to refrigerate the electrolyte to keep down the I^2R heating. Much glue is used in the cells; about 3 lb. is consumed for every ton of zinc produced. This keeps down the acid mist effectively; indeed the undue formation of mist is an indicator of the need of more colloid. Current efficiency averages 89 per cent of the theoretical electrochemical equivalent of zinc, with an input of 1.77 kw.-hr. per lb. of zinc. The 35-hr. cathode deposits are very dense and smooth, showing no signs of sprouting despite their thickness of $\frac{1}{8}$ in. Average extraction from a 39 per cent ore averaged 87.6 per cent for a fortnight's operations, figured on the weight of cathode sheets, about two tons of which are produced daily in the present plant.

The chairman, E. P. Mathewson, characterized the work of Tainton and Pring as being the final evidence that furnace methods for zinc production are doomed to extinction. Their experiments show that a small plant can be erected having a very large output, and only where natural gas is extraordinarily cheap and electricity extraordinarily dear can retort smelting show advantages in cost per pound of zinc.

STEEL CHIMNEYS IN COPPER PLANTS

"Steel Chimneys and Their Linings in Copper Smelting Plants" was the title of a paper by A. G. McGregor, in which he gave the structural details of a number of such erected in the Southwest, and a

record of their performance. From the data he concluded that unlined steel chimneys or chimneys or dust chambers lined with building tile have not given satisfactory service when used for roaster or reverberatory furnaces, but they have endured for long periods when used for blast-furnace and converter gases. Such results may be expected in ordinary copper plants where no especial effort is made to keep gases at a high temperature. Table I summarizes his data.

Unfortunately no explanation of the corrosion was ventured. Converter gases usually corrode metal flues badly, but Hiram Hixon advanced the opinion

Non-Ferrous Metallography

W. P. Sykes presented a paper on the "Effect of Temperature, Grain Size and Rate of Loading on the Mechanical Properties of Metals." This is a companion paper to one of the same title by Dr. Zay Jeffries,¹ appearing in the *Transactions* of the Institute for 1919 (vol. 60, p. 474), the two men working in conjunction in both researches. There are now two series of metals, W, Fe, Cu and Mo, Ni, Al, which have been carefully studied and the results are available to verify existing generalizations between atomic configuration and various

TABLE I. STEEL SMELTER STACKS

that this was caused by eddy currents between the hot gas and cold air drawn into the hood, producing a zone locally cooled below the dew point, with a resulting precipitation of acid. Further along, where the gas and entrained air had a chance to become thoroughly mixed and equalized in temperature, little precipitation occurred, with correspondingly small corrosion. His observations from Mexico and Canada convinced him that corrosion of metallic smoke ducts was a matter of humidity—keep the temperature above the dew point within the flue or chimney, and corrosion will occur only at the exit, where the out-flowing gas strikes a very wet or very cold atmosphere.

Forest Rutherford also agreed that the temperature of sulphurous gases should be relatively high if corrosion was to be prevented. During his superintendency at Copper Queen, the main stack—200 ft. high and unlined—venting the smoke from all departments, was kept hot continually. Even when the smelter was shut down a good fire was maintained at the base. This stack is still undamaged. Building tile and lime mortar are to be avoided because of the formation of gypsum with a large increase in volume—thus breaking up the continuity of the material. Roaster and reverberatory gases are different in their nature and corrosive action for many causes, not least of which is the moisture content of the furnace feed.

C. R. Kuzell also pointed out a controlling factor existing at the Clarkedale smelter, where a 30 x 400-ft. brick-lined steel stack discharges smoke from all departments. The ores contain some zinc, and enough of it is fumed during operations to neutralize acidity in the hot gases. Lacking available base of this sort, definite steps would doubtless be necessary to prevent corrosion.

easily observable physical properties. Of these six metals, X-ray investigations indicate that W, Fe and Mo crystallize in the body centered cube. Cu, Ni and Al, together with Pb, Pt, Au and Ag, assume the face centered cubic structure, and when equiaxed hold their ductility to the temperature of liquid air, as does also manganese steel. Here is a little light on the difference between gamma and alpha iron. Manganese steel, which is austenitic, shows a face centered cube under X-ray analysis. Consequently gamma iron is also thought to be of this crystallinity, whereas alpha iron, as above stated, is body centered. In common with tungsten and molybdenum, it is brittle instead of somewhat ductile in liquid air. Magnesium and zinc harden very rapidly under cold deformation, and appear to belong to the hexagonal system. In general, it may also be said that the rate of change in physical properties as the temperature varies is a function of the atomic weight—i.e., a change of say 100 deg. C. will make a greater change in the elongation of tungsten or lead than it will in the elongation of iron or aluminum.

ARTILLERY CARTRIDGE CASES

"Artillery Cartridge Cases" were discussed by J. Burns Read and S. Tour. They pointed out that since these cases are cold-worked from brass disks, it is essential first that the original disk be of good quality; second, that the tools and amount of cold work be correct, and third, the annealing heats between successive stamping or drawing operations be carefully controlled. Formerly only a rather loose chemical specification had to be met, pending final acceptance of the lot by ballistic testing. In the latter, three cases from each lot are fired at 12 per cent excess powder charge.

During the war no lots were rejected at this point, although 123 had to be retested, 72 of which were due to deficiencies in metallic structure and could have been predicted from the records of the metallurgical tests made by the government inspectors.

Physical tests on strips taken from two cases in each lot were utilized principally for the guidance of the manufacturer; good results were ordinarily obtained except at the end of the case, where varied amount of work and consequent error in the reheating temperature caused deviations. These tests have now been well established, and pending the development and general acceptance of a substitute in the form of a hardness test, should be put into the specifications as a requirement.

Microscopic observations on six locations in five cases from each lot proved of extreme importance in the control of correct manufacture. In general, typical micro-sections showed a well-defined re-crystallization at the mouth, hard metal in the wall behind the taper, and well-worked metal in the end.

Mercuric chloride tests on one case were also made for manufacturing control. As is well known, immersion for four hours in a 1½ per cent solution will develop intercrystalline cracks in metal where somewhat severe differential stresses produced by incorrect working or annealing exist, especially if they are tension stresses, and which later would result in those spontaneous and mysterious failures known as season cracking. No connection has been discovered between this test and the others, and whereas it caused many rejections from immature contractors, the difficulties could ordinarily be removed by giving close attention to the tool design, by increasing the work at the last redraw, and by increasing either the time or the temperature of the final anneal.

Session on Metallography of Iron and Steel

"Nitrogen in Steel, and the Erosion of Guns," by H. E. Wheeler, was printed for the Lake Superior meeting of last August, and abstracted in our issue for Sept. 1, 1920 (vol. 23, p. 366), as was also another interesting metallographical paper by Messrs. Hemingway and Ensminger on "Surface Changes in Carbon Steel Heated in Vacuo." Mr. Wheeler's work was on the cause of explosive rupture of gas containers, but in the course of the investigation he noted many similarities to surface conditions in gun tubes. Hardening and embrittling by nitrogen have been recently discussed in these columns by Knight and Northrup² and Fay.³ One statement made by Mr. Wheeler, that "iron nitride is no more metallic than iron oxide, and the writer seriously questions its ever having been found as a metallographic constituent of steel," was taken sharp exception to by both W. R. Ruder and George F. Comstock. These men, together with S. W. Miller, have shown that some nitrogen-bearing constituent is undoubtedly present in fusion welds. This may not be iron nitride, but it is quite distinctive and has been observed in carbon-free iron and steels up to 0.20 carbon, therefore it is not associated with a critical carbon content. Using the word "nitride" to signify this new constituent, it is known that pearlite and nitride cannot be distinguished by HNO₃ or picric acid etching. Ruder

and Comstock have had good results with a modified Stead's reagent,⁴ but the Bureau of Standards was not so successful in its use, since massive nitride is sometimes unattacked. Comstock now reports that a boiling reagent consisting of 10 g. KOH, 1 to 4 g. potassium ferricyanide, in 100 c.c. water, if applied from ten to thirty minutes will give a sharp distinction. Massive cementite is blackened, massive nitride is attacked only slightly, becoming yellowish in tone, while pearlite is etched at an intermediate rate, assuming a distinctly brown tint.

Reaction Between Iron, Carbon and Oxygen

A. Matsubara, of the University of Kyoto, Japan, has made some fundamental studies in the "Chemical Equilibrium Between Iron, Carbon and Oxygen."

The long and painstaking work may be reviewed under several heads:

(1) In properly constructed and operated apparatus, the equilibrium compositions of the gases CO and CO₂ in contact with metallic iron and ferric oxide were carefully measured at 863, 1,070 and 1,175 deg. C. Over 100 separate tests were made in this one study. The net results show that the following percentages of CO are in equilibrium with the following substances at the temperatures stated:

	863 Degrees C.	1,070 Degrees C.	1,175 Degrees C.
Fe ₂ O ₃	0	0	0
Fe ₃ O ₄	25	15	15
FeO.....	67	72	75

The first line means simply that at the temperatures used, Fe₂O₃ dissociates of itself into Fe₃O₄ and O so strongly that any CO present is oxidized to CO₂ and no equilibrium exists; or, putting it another way, any percentage of CO will reduce Fe₂O₃ to Fe₃O₄ at any of these temperatures.

The second line means that Fe₃O₄ is reduced to FeO by any mixture containing more than the percentages of CO given, at the temperatures named.

The third line indicates that FeO is reduced to Fe by any mixture richer in CO than the percentages given.

In each case, the percentage of CO means the proportion it forms to the sum of CO and CO₂ present, ignoring the inert nitrogen which may accompany it in the blast or other furnace. Diagrams are given which summarize the various tests.

(2) From these data, the author has calculated Tables

TABLE I. VALUES FOR FeO:Fe EQUILIBRIUM

Temperature Degrees Absolute	Per Cent CO	(Equilibrium Constant) Log K	Log P	P*
834	0.536	8.2530-10	8.4618-10	0.029
935	0.584	9.4400-10	9.5263-10	0.336
993	0.607	0.0181	0.0461	1.112
1,136	0.659	1.2085	1.1035	12.7
1,236	0.692	1.8914	1.6997	50.1
1,343	0.724	2.5218	2.2432	175.0
1,448	0.755	3.0618	2.6999	501.0

I and II, giving the gas pressures exerted at different temperatures by FeO and Fe₃O₄, respectively, in presence of C as a reducing agent.

It must be remembered that in the blast furnace these are in reality partial pressures, being that fraction of the total tension of the gases borne by the CO and CO₂ present. The author further calculates the simple

³"Nitrogen and Case-Hardening," vol. 24, p. 289 (Feb. 16, 1921).

⁴Consisting of 0.1 g. mercuric chloride, 0.1 cupric chloride, 20 c.c. concentrated HCl and 80 c.c. ethyl alcohol. This is dropped on the sample, and the pearlite rebrightened by gentle polishing, repeating the process until a satisfactory contrast is had.

TABLE II. VALUES FOR $\text{Fe}_3\text{O}_4\text{:FeO}$ EQUILIBRIUM

Temperature Degrees T Absolute	Per Cent CO	(Equilibrium Constant) Log K	Log P	P^*
900	0.435	9.0574-10	9.5325-10	0.341
993	0.352	0.0181	0.7366	5.453
1,136	0.255	1.2085	2.3763	236.8
1,236	0.204	1.8914	3.1730	1,489.0
1,343	0.164	2.5218	4.0143	10,335.0
1,448	0.152	3.0618	4.6265	42,320.0

* These values of P represent the total equilibrium pressure of the system containing amorphous carbon.

dissociation pressures of the compounds Fe_3O_4 and FeO , at temperatures from 800 to 2,400 deg. absolute. These data are of great scientific interest, but do not apply directly to blast-furnace practice, where C is always present.

(3) The reactions by which iron absorbs carbon and becomes carburized are next studied. They involve either the action of CO on reduced Fe or of CO on FeO which is being reduced to Fe; that is, either

The results of about forty experiments prove that the first period of carburization in the blast furnace corresponds to the second of these reactions, and at a later stage to the first reaction; there exist transitional equilibria between. These reactions proceed from left to right at fairly low temperatures. Table III gives the percentage of CO present at equilibrium in each of these reactions at various temperatures, and in other extensive tables the equilibrium pressures exerted at various temperatures for various percentages of CO.

TABLE III. EQUILIBRIUM POINTS OF CARBURIZING REACTIONS

Temperature Deg. C.	Percentage CO at Equilibrium	
	$3\text{Fe} + 5\text{CO} \rightleftharpoons \text{Fe}_3\text{C} + 4\text{CO}_2$	$3\text{FeO} + 2\text{CO} \rightleftharpoons \text{Fe}_3\text{C} + \text{CO}_2$
685		55.48
743		75.49
744		76.00
761		80.81
772	80.22	
810	84.58	
814		88.09
857		89.68
907	89.15	
909		92.45
963		93.90
965	91.05	
968		93.90

1,014	93.12	
1,065		96.64
1,070		97.27
1,176	97	

Three applications of these principles are studied—viz., to case-hardening, malleabilization, and blast-furnace reactions.

In *case-hardening*, the author shows that Schenck's assumption that the isothermals of $\text{Fe:Fe}_3\text{C}$, $\text{FeO:Fe}_3\text{C}$ and FeO:Fe meet in a common point is untenable and contradicted by his data; this renders Giolitti and Carnavali's diagram, based partly on Schenck's assumption, also untenable, and leads to a quite different diagram. These matters have been discussed in METALLURGICAL & CHEMICAL ENGINEERING, April 1, 1917 (vol. 16, p. 385), and will be treated at length subsequently.

In *malleabilizing* that which it is desired to oxidize is iron carbide and not iron itself. The reaction should, therefore, be confined to

and not to be extended to

Then, it is clear that the oxygen-dissociation pressure of the gas surrounding the cast iron that is to be

malleabilized should be always a little higher than corresponds to the $\text{Fe:Fe}_3\text{C}$ equilibrium proper to the adopted pressure; any larger excess of oxygen pressure should be avoided, as otherwise iron would be oxidized. This regulation of pressure can be performed by one of the following methods:

1. By the regulation of the velocity at which CO_2 , O_2 or air is introduced into the reaction vessel.

2. By the regulation of the composition of the oxidizing gas; for instance, the ratio of CO:CO_2 when a mixture of these gases is employed, the ratio of $\text{O}_2\text{:N}_2$ when air is employed, etc.

By the analysis of the escaping gas the oxygen pressure of the reacting gas is easily determined, it is only necessary to determine the ratio $\text{CO: (CO + CO}_2\text{)}$ in the gas, for the volume percentage of oxygen is negligible.

In the *blast furnace*, the influence of varying temperatures, varying pressures and varying compositions of gas form a highly complex problem. Assuming the CO plus CO_2 to constitute an average of 36 per cent of the volume of the gases in the furnace, the sum of their partial pressure is fixed, and the problem becomes soluble. Taking the pressure and temperature distribution in the furnace as determined by Schlesinger as typical, the partial pressures of CO plus CO_2 at the determined pressures become known, and the equilibrium conditions can be studied at various points in the furnace. This study leads to a remarkably instructive diagram, which shows in brief, that ferric oxide and magnetic oxide are reduced to FeO easily, but that the main reducing power of the furnace is used for the reduction of the ferrous oxide at 900 to 1,000 deg. C. The reactions are further effected by the displacement of equilibrium due to the CO_2 from the limestone. The effect of removing moisture and enriching the blast in oxygen are evidently deducible from a study of the equilibria data determined in this investigation.

Fluorspar Industry in Germany

The largest fluorspar fields in Germany are situated in the Hartz, Upper Palatinate, Thuringian Forest and Black Forest. The best quality is produced in the Upper Palatinate. The fluorspar found in the Upper Palatinate contains generally from 95 to 98 per cent of fluoride of calcium and relatively little silicic acid.

Most of the fluorspar is consumed at present by the iron industry. In the case of this kind of utilization, broken materials suffice. Other consumers are the glass industry and the chemical and enamel industries. These utilize fluorspar in a milled form, and together they use much less than the iron industry alone. According to a rough estimate made before the war it is calculated that the quantities supplied, respectively, to the individual industries are approximately as follows: Iron and metal smelting industry, 79 to 84 per cent; glass industry, 10 to 15 per cent; chemical industry, 5 per cent; enamel industry, 5 per cent; optical industry, 5 per cent.

The utilization of fluorspar in the iron industry has made steady progress in consequence of the shortage of coal since the armistice, since fluorspar increases the fluidity of the fusible material and thus effects an economy of fuel, although at the cost of the quality of the resulting product. Consequently, it is probable that post-war statistics will show an increase of the consumption of fluorspar by the iron industry at the expense of that of the glass industry.

Armour Fertilizer Works—I

New Plant at Chicago Heights, Ill., Now in Operation—Model Chamber Process Producing Sulphuric Acid From Sulphur—Methods of Tower and Chamber Construction and Liquid-Handling
Mark Advance Practice in Chemical Engineering

BY CHESTER H. JONES

THE new plant of the Armour Fertilizer Works which has recently been brought into full operation at Chicago Heights, Ill., is an admirable example of what may be accomplished by the application of chemical engineering and the science of chemistry in the design of process and the operating control of a most essential industry. An extensive variety of mixed fertilizers for adaptation to any combination of soil and crop is produced with the control so carefully worked out in the blending of each lot of material that the actual chemical formulas may be stamped on every sack before shipment to the trade.

Mixing under the supervision of the chemist is, however, only a feature of the final stages of manufacture which will be later described.

One of the important initial steps is the manufacture of sulphuric acid from sulphur. The large building on the left in the illustration at the top of this page houses the sulphuric acid plant complete with the chambers as seen on the left, the towers in the intermediate high bay and the sulphur burners in the lower lean-to on the right.

This is probably one of the finest chamber plants in the United States. All the piping, flues, pumping systems, chambers, coolers, towers and tanks are so designed as to contain and convey the materials without the least evidence of mist, spray, fume or acid slop

at any point in the process. The stack where the final gases are emitted to the atmosphere with the plant in full operation never displays the slightest visible trace of either mist or niter fume.

SULPHUR BURNING

The commercial sulphur is obtained from Southern companies, and arriving in box cars is shoveled to the storage pile in the end of the burner room. Thence it is drawn in wheelbarrows weighed over a Standard

platform scale and delivered to the burner doors as shown in Fig. 1. Twenty-four tons of sulphur is consumed every twenty-four hours to produce about 117 tons of 50 deg. Bé. H_2SO_4 . The burners were designed by Armour Fertilizer Works engineers, the construction being essentially two units of six chambers each with common brick walls and firebrick arches and linings. Steel buckstays and rods support the walls and arches and the doors and frames

FIG. 2. TOP OF BURNERS AND EXIT FLUE

are made of cast iron. This constitutes all the metal work. There are no moving parts, sulphur simply burns on the hearths. Air is admitted in sufficient quantity to volatilize the sulphur to sulphur dioxide, the reaction being completed by the time the gases reach the exit flue. Fig. 2 shows this flue over the top of the burning chambers. It is placed between the two units, drawing gas from a common header. It is constructed from sheet steel lined with a double course of firebrick.

Located near the foot of the stack are three niter

FIG. 1. FIRING DOORS OF SULPHUR ROASTERS

FIG. 4. ACID COOLER, SHOWING COILS BENEATH SURFACE

pots each 5 ft. long by 3 ft. wide by 3 ft. deep, cast by the Chalmers-Williams Co. The Chilean nitrate purchased on the open market is put into these pots and treated with sulphuric acid piped from the Glover tower outlet trough. (See Fig. 3.)

ACID TOWERS

The piers and floors supporting the brickwork of the towers proper are reinforced concrete. The steel framework surrounding and supporting the brick structure is heavily painted with asphaltum, and lead sheet is burned around the steel footings to protect from possible acid fume or slop. The lead pans (40-lb. lead) in which the brick floor of each tower is laid are first lined with asbestos paper and a $\frac{3}{4}$ -in. layer of sulphate of lead mud.

GLOVER TOWER CONSTRUCTION

Three courses of brick laid flat constitute the floor of the Glover tower. Above the brick arches checkerwork of chemical brick is laid on edge for twenty-eight courses, commencing with 3-in. spaces between brick at the lower course and having $1\frac{1}{4}$ -in. spacing on the top course. The space above the checkerwork is filled for a distance of 9 ft. with quartz graded up from 6-in. size to 4-in. on the top layer. This completes the packing. The brick walls grade up from 20-in. thickness in the space occupied by the arches to 8 in. thick at the top of the tower. The brick is laid in silicate of soda up to top of lead pan (19 in.), the remainder being laid dry. The brickwork is surrounded outside with sheet lead supported by steel framework. The top is 14-lb. sheet lead.

GAY-LUSSAC TOWER CONSTRUCTION

These three towers are constructed after the same manner as the above except the space above the arches is filled with 6-in. diameter by 6-in. long spiral chemical tower packing for about forty-five layers and with 3-in. diameters by 3-in. long spiral rings for sixteen layers' distance at the top. The walls are 10-lb. lead sheathing with 4-in. brick lining laid dry. The top is 12-lb. lead sheet. All lead is supported from steel framework.

ACID COOLING TANKS

The coolers shown in the plan (Fig. 3) located at the foot of the Glover tower are further illustrated in Figs. 4 and 5. They are arranged to convey the acid either three in series or so that the first cooler may be bypassed. The acid is delivered from the last cooler at 60 deg. Bé. and 100 deg. F. (38 deg. C.).

Each cooler is supplied with five separate streams of

water as shown by the piping in the foreground, Fig. 5. Four of these leads connect into the four lead pipe coils seen beneath the surface of the acid in Fig. 4. After passing through these coils the waste cooling water empties into the basin at the left. These four waste pipes are shown leading into this catchbasin. It will be noted that the tanks have double walls with an annular space between. This space receives the fifth stream of cooling water from the vertical header, as shown in Fig. 5, and is discharged by a short connection to the same catchbasin as the four coil waste leads. There is space within each cooling coil for the addition of auxiliary coils as increased rate of plant operation may demand. The sixth lead as noted at the top of the manifold in Fig 5 is connected with an extra coil so inserted.

The acid flows from the Glover to the inner tank of the rear set (see Fig. 5) and overflows to the inner tank of the second set, thence to the third set. The complete flow of acid through the system of pipes and receiving tanks may be traced in Fig. 3. Water in this locality is very scarce, so all waste water from the coolers is carried to the cooling pond shown in front of the acid plant in illustration top of page 333. This water is handled by a 175-gal. Gould centrifugal pump direct-driven by a General Electric motor.

ACID-PUMPING SYSTEM AT TOWERS

The usual method of elevating acid over the towers by compressed air acid lifts has been departed from in the construction of this plant and after some experiments and tests the centrifugal pump was decided upon. Various economies have been claimed by manufacturers of both types of apparatus and each type has its merits as applied to individual installations and particular kinds of acid pumped. In this case the pumps have been operating continuously over a period of some months with a satisfactory showing.

The location of these pumps in the basement is shown in Fig. 3, and the illustration Fig. 6 is an interior view of the basement along the line of pumps and between

the two rows of tanks. These machines are manufactured by the Chemical Equipment Co., Chicago, and are direct-connected to 5-hp., 1,750 r.p.m., three-phase, sixty-cycle Westinghouse induction motors, operated through controllers and cut-out switches of the totally inclosed type. These latter are seen mounted on the steel columns in Fig. 6 and are manufactured by the Trumbull Electric Mfg. Co., Plainville, Conn. Each pump has a $2\frac{1}{2}$ -in. suction and 2-in. discharge. The flow is controlled by a valve on the suction side so that a small

FIG. 5. ACID COOLERS, SHOWING COOLING WATER SUPPLY PIPING

FIG. 6. ACID PUMPS AND TANKS IN BASEMENT

amount of air is drawn in through the stuffing box, obviating any acid leakage at this point. No vibration is noticeable when the pump is running at full speed, and it is therefore not necessary to bolt the base plate to the concrete foundation. All seven tanks on the first floor are independent, one pump drawing from each tank. The large tank on the left rear, Fig. 6, contains the supply of 53 deg. Bé. acid for the fertilizer plant. The connections for all pumps, including the line to the fertilizer plant, are shown in Fig. 3. Note that all lead plugs about the acid plant, upper right hand, Fig. 7, are conveniently operated by levers connecting to plunger rods made adjustable by means of set screws.

TANK FLOOR

The top floor over the acid towers supports five acid tanks as shown in plan and elevation, Fig. 3, and illustrated in Fig. 7. These tanks, as well as those in the basement, are built up from 2 x 8, 2 x 6 and 2 x 4-in. timbers laid on side, as shown, the whole being painted with black asphaltum, and lead lined. Each tank is equipped with splash box, shown near the posts, Fig. 7,

FIG. 7. ACID TANKS OVER TOWERS

and on the right in Fig. 8, with double float siphon and with float connected to telltale in basement for determining height of acid.

Fig. 8 shows the inside of one tank containing acid. The two large floats with the container between and into which the bent pipe leads constitute the double float siphon. This is so arranged as to deliver acid to the distributors on the floor below under constant head and flow. The large telltale float appears in the lower right-hand corner. The splash box in the upper right-hand corner receives the acid as it is pumped up from the basement tanks.

DISTRIBUTION FLOOR OVER TOWER

Fig. 9 shows one of the distributing pans with leads running into top of tower. The horizontal, lead-covered, steel rods carry the straps, which in turn support the lead roof of the acid tower proper. The pan, consisting of timber frame, lead-lined, is supported on two 6-in. double channels suspended from the roof trusses by 1-in. rods, each provided with turnbuckle adjustment.

An interior view looking down on top of the pan, Fig. 10, shows the rectangular gage box on the left, the

FIG. 8. INSIDE OF ACID TANKS

lead pipe leading from the bottom of this gage box into the side of the dome-shaped splash box. This latter is located in the center of the pan and permits the acid to flow into the pan through perforations. This in turn flows into the lutes, which are sealed to prevent the escape of tower gases by inverting ordinary glass tumblers as customarily practiced. The pipe leading into the top of the gage box, on the left, Fig. 10, comes directly from the double float siphon, as described, on the floor above. The complete arrangement appears in outline in Fig. 3.

As indicated in Fig. 3, the chamber system consists of six chambers in series. The fume passes from Glover

FIG. 9. DISTRIBUTION PAN ON TOWER FLOOR

FIG. 10. INTERIOR OF DISTRIBUTION PAN

and 3, the other between 3 and 4. These increase the efficiency of the system by serving as additional acid-making areas. They are built after the manner of the Gay-Lussac towers and filled with thirty-three layers of 6-in. spiral chemical tile.

The entire chamber system is supported on steel columns from beneath and each tower and chamber is constructed with steel framework, the whole being housed in a steel building sided and roofed with Keasby & Mattieson acid-proof corrugated asbestos.

The method of supporting the lead curtain walls of the chambers is well shown in Fig. 11. The steel channel girts with flanges turned upward carry 4 x 4-in. timbers rounded on the upper side. V-shaped lead straps were burned onto each lead sheet as erected, with the straps bent over the rounded timber and nailed as shown. When the weight of the curtain was thus gradually thrown on these straps they were slightly torn at the nail holes, permitting an equalizing sag at various points and so distributing the load as to obviate any wrinkles in the curtain. The excellent results obtained are evident to the most critical inspector. The roofs of the chambers were supported by loops of lead strap from I-beams in the same way as shown in the case of the tower roofs. (See Fig. 9.) Other evidences of excellency in the lead worker's art

FIG. 11. SIDE OF ACID CHAMBER

tower to chamber 1 and leaves chamber 6 by way of the overhead fume line, thence through Gay-Lussac towers 3 and 2. From tower 2 it is drawn through the Pratt exhauster, delivered to Gay-Lussac tower 1 and proceeds onward through the system. The exhauster is driven by a variable speed reducer as shown in Fig. 3, which permits changing the speed of the exhauster while running. Two intermediate towers are located in the chamber system, one between chambers 2

are shown in Figs. 11 and 12. The funnel in Fig. 11 is used for washing out the trough inside the chamber which slants downward to the test basin shown in Fig. 12. Here the hydrometer tests are taken, as well as the temperature readings from the thermometer directly above.

ACID SYSTEM AND SPRAYS

All chamber pans are so interconnected by lead piping that acid may be drawn from any single chamber or combination of chambers. Mixing acid for the fertil-

izer plant is drawn from the first chamber. The weak acid is carried over the Glover tower. No steam is furnished to the system. The water is introduced at the tops of the chambers through a series of stone cap and spiral $\frac{3}{4}$ -mm. Monarch sprays. The weak acid in the Glover tower generates enough steam in the gases to be effective through the first three chambers, but is supplemented by the water sprays beginning with the second chamber. The sprays are supplied with water from a pair of air pressure tanks located in the

FIG. 12. TEST BASIN ON SIDE OF CHAMBER

basement, connected up with the National Brake & Electric Co. automatic air compressor, maintaining a constant head of 70 lb. While one tank fills with water from the mains the other is emptying under pressure to the spray system.

The operation of the entire sulphuric acid unit has exceeded the expectations of the designers. The visitor after viewing the installation and its operation would call it a perfect acid plant.

The fertilizer plant and acid phosphate manufacture will be described in a subsequent issue.

Varieties of Kongo Trees Producing Tannin

According to a recent article in the *Exportateur Belge* there are numerous trees in Kongo with barks rich in tannin. Among these is the Mwena, a species of mangrove abounding on the banks of the Lower Kongo and its tributaries, the bark of which contains a minimum of 15 per cent of tanning matter, the trunk and the roots producing an extract running from 50 to 55 per cent of tannin. The wood itself, which is hard and undecaying, is a valuable byproduct adapted for use in the construction of piling, railroad sleepers and ships. Several varieties of the *Terminalia* give barks which render a dry extract entirely soluble when cold and containing 62 per cent of tannin. This extract produces an extremely light and well-tanned leather.

Other varieties of native trees also produce tannin extracts, hence the tanbark industry is one of great potential importance for the Kongo.

Causes of Piping in Aluminum Ingots

Measurements of Piping and Solidification Shrinkage Show That the Volume of a Pipe Is Dependent on Four or Even More Definite Factors, and That It Is Not a Specific Property of a Metal or an Alloy

By JUNIUS DAVID EDWARDS* AND HAROLD T. GAMMON†

IN THE preceding papers (CHEMICAL & METALLURGICAL ENGINEERING, Vol. 24, Nos. 2 and 5, pp. 61 and 217) the density of aluminum and the copper: aluminum alloys at temperatures from 20 to 1,000 deg. C. were given. From these data the complete density curves were constructed for this range of temperatures, and the solidification shrinkage was estimated with good precision. Solidification shrinkage is responsible for the piping of the metal when it is cast, and because the extent to which piping occurs is a factor in determining the suitability of a metal for casting purposes it seemed desirable to analyze the relation between the amount of shrinkage and the observed piping. An attempt has therefore been made to determine quantitatively the amount of piping which occurs in casting aluminum and some of its alloys. Although this attempt was not entirely successful, mainly because the amount of piping which occurs is far from being a definite quantity, nevertheless the work has led to a much clearer conception of the factors controlling the formation of pipes in castings. This article is in the nature of a memorandum of experiments completed and conclusions reached, rather than a complete summary of the problem.

MECHANISM OF FORMATION OF PIPES

Before considering the problem of the pipe it will be well to consider the volume changes which occur on freezing. In Fig. 1, Curve A, is shown the relation between temperature and specific volume, which is the volume in milliliters per gram of pure aluminum. Starting with the liquid metal, the contraction on cooling is slow and uniform until the freezing point is reached; at this temperature a large contraction in volume takes place during the solidification. The solid metal then contracts slowly, but at a somewhat different rate from the metal in the liquid state. Curve B shows the same relations for an alloy of aluminum with 4 per cent of copper. The most characteristic difference to be noted is that solidification no longer takes place at constant temperature, but over a considerable range of temperatures, amounting in this case to approximately 100 deg. C. Curve C shows the change in specific volume of the alloy of aluminum with 8 per cent copper. This is somewhat different than in the preceding case, because part of the solidification takes place at constant temperature. The 8 per cent copper alloy contains approximately 15 per cent of the eutectic mixture when it has cooled to a temperature of 540 deg. C. and this eutectic freezes at constant temperature in exactly the same way as a pure metal. These three curves show the characteristic volume changes on freez-

ing of the pure metal and two of its important binary alloys.

Briefly, the formation of the pipe in casting an ingot takes place in somewhat the following manner: The metal which is in contact with the walls of the mold cools to the freezing temperature first, and there solidifies to form a solid shell which grows in thickness by the continued solidification of the metal. Because there is a contraction in volume of the metal upon solidification, the level of the liquid contained within this shell of frozen metal is continually lowered during the course of the freezing. If no additional metal is supplied during the freezing process, a conical-shaped cavity known as a pipe is formed. The main function of the gates and risers is to supply the metal required to keep the mold completely filled during the solidification and consequent contraction of the metal contained in it. With reference to Fig. 1, Curve A shows that the contraction on freezing in the case of

FIG. 1. RELATION BETWEEN TEMPERATURE AND SPECIFIC VOLUME

*Physical Chemist, Aluminum Company of America.

†Chemist, Aluminum Company of America.

pure aluminum is about 6.6 per cent, and consequently 6.6 lb. of aluminum must be fed into the casting from the gates for every 100 lb. of casting. In the case of the 4 per cent and 8 per cent copper alloys the contraction upon freezing is of approximately the same magnitude.

The volume of the pipe is not, however, necessarily equal to nor proportional to the contraction upon freezing. In the case of pure aluminum the two are very nearly alike. That this is nearly so comes from the fact that the shell first formed in the casting of the pure metal is quite rigid, and the contraction during freezing necessarily appears in the form of a central cavity. In the case of the alloys, however, the solid which separates during the first part of the freezing process is a network of crystals more or less interpenetrated by liquid. This mixture may be quite plastic and the shell which first forms in the mold is not so rigid as in the case of the pure metal. This is of advantage in casting practice, because it permits the casting to adjust its form somewhat upon cooling without straining the cores or other fragile parts of the mold. As a result, the mixture of partly frozen metal within the mold behaves as if it was still liquid for a considerable interval of temperature below the commencement of freezing. As a consequence the volume of the pipe which is formed with the alloys is less than is the case for the pure metal. The apparent volume of the pipe may also be reduced in some cases by the formation of a porous structure at the top of the ingot, gate or riser where the final freezing occurs. This happens if the network of crystals at the surface possesses sufficient rigidity to allow the eutectic to withdraw from between the crystals during its solidification, thus leaving voids in this part of the metal. Part of the pipe is then disseminated and concealed within the body of the metal.

EXPERIMENTAL METHOD

The following method was employed to determine the relative piping effect with different metals: A graphite crucible having a capacity of approximately 225 c.c. was filled with slightly more than that volume of molten metal, after which a hot iron plate was pressed down upon the surface of the crucible and the metal. The plate forced out the excess metal so that the crucible contained exactly its known volume of metal at that average temperature. After the metal had solidified, the ingot was removed and the exact volume of the pipe was determined by filling with mercury and then weighing the mercury. A piece of paraffine-coated paper with a straight edge was wrapped tightly around the ingot and fastened in place in order to sharply define the upper edge of the pipe in case it was irregular or not level. An attempt was made, by controlling the pouring temperature, to have the metal freeze sharply at the edge of the crucible, so that the volume of the pipe might be sharply defined. This was a difficult condition to obtain with most of the alloys. The pipe in the ingot is measured at room temperature, and is therefore smaller than it was at the freezing point of the metal, because of the shrinkage of the metal in the solid state. The correction for this has been calculated from the solid shrinkage of the metal and the volume of the pipe then expressed as a percentage of the volume of the mold, which volume was the original volume of the ingot before cooling.

The solid shrinkage, which is the relative change in

volume of the solid metal in cooling from the freezing point to room temperature, was determined by casting in a sand mold a bar about 2 ft. long. The ends of the mold were formed by two graphite blocks which were rigidly held a known distance apart by steel plates; these were so arranged that the heat from the metal did not cause any appreciable expansion of the steel plates before the metal in the mold had set. The space between these graphite blocks was filled with solid metal at the freezing point. Knowing the distance between the graphite blocks and the length of the bar when cold, the shrinkage expressed in inches per foot of original length may be readily calculated.

The results of a series of measurements on the volume of pipe and the solid shrinkage of aluminum and some of its alloys with copper are given in Table I.

The observed piping effect with the aluminum was 7.7 per cent, and with the 8 per cent copper: aluminum

TABLE I. THE PIPING EFFECT IN ALUMINUM AND ITS ALLOYS

Composition	Volume of Crucible, ml.	Pouring Temp., Deg. F.	Solid Shrinkage, Inches per Ft.	Volume of Pipe, ml.	Corrected Volume of Pipe, ml.	Piping Effect, Per Cent
Aluminum, 99.4%.....	239	1,550	0.21	17.4	18.3	7.7
Al+ 4 Cu.....	223	1,300	0.19	9.6	10.0	4.5
Al+ 6 Cu.....	223	1,300	0.18	9.4	9.8	4.4
Al+ 8 Cu.....	239	1,300	0.18	8.7	9.1	3.8
Al+ 10 Cu.....	223	1,300	0.17	6.8	7.1	3.2
Al+ 12 Cu.....	223	1,300	0.17	6.7	7.0	3.1
Al+ 31 Cu.....	223	1,300	0.15	12.4	12.9	5.8

alloy was only 3.8 per cent. This at first appears anomalous, in view of the fact that the solidification shrinkage is approximately the same in both cases (6 to 7 per cent; see "Mechanism of Solidification of a Copper: Aluminum Alloy," CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, No. 5, p. 217). A reasonable explanation for this difference in behavior has already been given in a preceding paragraph. It may be illustrated more clearly by reference to Fig. 2, where the

FIG. 2. VERTICAL SECTIONS THROUGH CENTER OF INGOTS

experimental ingots for the pure aluminum and the 8 per cent copper alloy are shown in section. It will be noted that the ingot of No. 12 alloy is shorter than the aluminum ingot and that the upper edges are very much rounded off, whereas in the aluminum ingot the metal has frozen sharply at the edge of the crucible. In the aluminum ingot the total contraction during solidification is represented by the volume of the pipe. In the alloy ingot part of the contraction has been

taken up by a readjustment of the shell initially formed in the mold, a fact which is attested by the appreciably shorter length of the alloy ingot. This difference in length is more striking when it is considered that the linear shrinkage of aluminum after solidification is greater than that of No. 12 alloy. In the case of the ingot of No. 12 alloy shown in the figure, its average length was about 11.2 cm., whereas it should have been nearer 11.7 cm. in length if the crystals had remained in place as they solidified at the walls. When allowance is made for this fact, it is found that the total solidification and liquid shrinkage was about 6.3 per cent, which is in fair agreement with the contraction indicated by the graph, making due allowance for the approximate nature of the measurements made on the ingot.

The piping effect gradually decreases with increase of copper, but there is very little decrease noted beyond 10 per cent. However, the sample containing 31 per cent copper and which is very nearly of eutectic composition shows a larger pipe than some alloys of lower copper content. This is what might be expected from our analysis of the mechanism of piping, because the eutectic alloy in freezing behaves essentially as the pure metal. Consequently there should be some alloy of intermediate composition which would show a minimum piping effect.

The volume of pipe formed in any given alloy is a complex function of the following factors: (1) The percentage contraction during solidification; (2) the rate of solidification during the freezing interval; (3) the temperature range of the freezing interval; (4) the size and form of the mold and probably some other conditions. Because the volume of the pipe is dependent on conditions external to the metal, it is not even certain that different alloys would give the same relative piping effect in one mold that they would in another. It is, accordingly, impossible to describe piping as a definite property of a metal. The contraction upon freezing is, however, a perfectly definite property which can be defined and measured and is the fundamental cause of piping. The values given in the table should therefore be considered in the light of this discussion whenever any use is to be made of them. It should also be borne in mind that the casting properties of a metal are not solely defined by the piping effect. It is only one important factor to be considered. A low solid shrinkage, for example, is of course very desirable in a casting alloy in order that the strains which are set up in a casting on cooling may be reduced to a minimum.

SUMMARY

A method of determining the piping effect in metals is described, and the results of measurements on a series of copper:aluminum alloys are given. It is shown that although the solidification shrinkage of a metal is responsible for the formation of the pipe, it is not necessarily proportional to it. The good casting properties of the 8 per cent copper alloy are not to be ascribed to a low solidification shrinkage (which it does not possess), but to the manner in which it freezes. The explanation given is not offered as a general formula for all alloys, but it is thought that the results obtained may be suggestive and helpful in many other cases.

Research Bureau,
Aluminum Company of America,
New Kensington, Pa.

Graphite Situation in Ceylon

Consul Robert L. Keiser of Colombo reports that the graphite trade of Ceylon reached a minimum in 1919, dropping from an exportation of over 33,000 tons in 1916 to 6,671 tons in 1919. The first five months of 1920 showed a slight increase, 4,235 tons having been exported. Of this amount the United States took 2,800 tons, or about 70 per cent of the total.

COMPARATIVE EXPORTS FOR RECENT YEARS

Exportation for the last four years has been as follows, the figures for 1920 being for five months:

Countries	1917, Tons	1918, Tons	1919, Tons	1920, Tons
United States.....	21,965	8,178	3,995	2,800
United Kingdom.....	4,600	6,386	2,260	1,062
India.....	145	293	88	31
Australia.....	237	288	146	188
Japan.....		61	80	117
All other.....	200	11	102	37
Total.....	27,047	15,217	6,671	4,235

The great slump in exportation has led to the closing of the majority of the small mines. During the peak of production (1917) about 1,300 mines were in operation, but at the beginning of 1920 less than fifty mines were working. It should be noted, however, that most of the mines in operation are those which are able at short notice, or with little preparation, to mine the bulk of the production.

COMPARATIVE PRICES

The average value per ton of all grades of graphite exported in 1913 was \$110 (330 rupees) and in 1917 about \$300 (900 rupees). In 1918 this figure decreased to about \$100 (300 rupees); in 1919, to \$104 (260 rupees); in 1920, to \$105 (230 rupees). It is difficult to estimate these values in terms of dollars, owing to the rapid fluctuation of exchange.

It is interesting to note that in 1913 the average value of graphite exported to the United States, United Kingdom, and Germany (these being the three largest consumers in the order named) was about the same for each of these countries. In 1918 the average value of the graphite exported to the United States was about \$130 per ton, against \$80 for the United Kingdom, and a general average of \$100. In 1919 the imports to the United Kingdom averaged \$70 per ton, while those to the United States were valued at \$130, the general average having been \$104. Statistics for the 1920 period show that the average values of exportation to the United Kingdom and the United States are again about the same, namely, \$108 and \$113, respectively.

No statistics are available covering production costs. The producers claim that on the present basis of prices there is not sufficient profit to make production interesting to them. Since 1913 wages have increased about 25 per cent. Barrels for packing, which formerly sold for 12.50 rupees, now cost 25, and the increased cost of explosives is large. It is therefore evident that but little profit is left to the miners at the present average price.

With the exception of three companies the mining operations are all in the hands of natives. There is no restriction against foreign companies owning mining properties or carrying on mining operations.

The Ceylon government assesses an ad valorem duty of 3 per cent on all graphite exported from the island.

Plant Design for Hot-Gas Pyrolytic Distillation of Shale

Description and Plan of a 2,000-Ton per Day Shale Oil Plant Operating on Indirect Heating Process
Employing Hot Gases for Conveying Reacting Heat and Resultant Oil
Vapors From Pyrolysis of the Shale

By LOUIS SIMPSON

AT THE present time it is no longer necessary to point out that the consumption of hydrocarbon oils has overtaken the supply; that the amount of such oils obtainable from the hitherto source of production is probably close to the maximum and that the world's ever-increasing requirement must in the future be secured from new sources of supply.

It is probably superfluous to state that such much-to-be-desired new sources of supply have been found in the oil-yielding shales, sands and rocks that are known to exist on all continents and in many districts of each continent. Admitting that such new sources of supplies exist, it must be confessed that the crux of the whole question is the availability of economic methods by which the volatile contents may be recovered from them at a cost that will give sufficient monetary return upon capital invested in their operation.

The world's requirements cannot be satisfied unless works of commercial capacity are operated. Even shales that are relatively lean in volatile contents must be profitably retorted where conditions are not unfavorable. It is not sufficient that works and processes be developed that will commercially retort shales very rich in kerogen. It is not desirable that shale works be erected for the production of other than standard oil products with the expectation that these specialties can be marketed at high prices. The markets for such specialties would soon become oversupplied, with the result that their manufacture would cease to be remunerative.

It is necessary that works be erected and processes used that will make possible the retorting of relatively lean shales at a profit when selling the manufactured products in markets that are not likely to become depressed through competition.

FUEL SUPPLY MOST IMPORTANT QUESTION TODAY

The year 1920 has proved that a constant and an assured supply of fuel at reasonable prices is the most important question on this continent today. Without an adequate supply of fuel there would have to be a reconstruction of the industries of many parts of the American continent. The present development of hydro-electric power and the possible future development of such power may mitigate but cannot solve this difficulty. Fuel to produce light, heat and power, fuel that can be readily and, as to cost, reasonably transported to the place where it is to be consumed, is today a necessity.

Years ago the world relied upon the combustion of wood and peat for the required heat and upon the combustion of fats and oils (vegetable, animal and fish) for the very indifferent quality of light with which the inhabitants of the world had to be content in those days. Today the wood and peat are largely replaced by coal, hydrocarbon oil, natural gas and electricity. Of these

the natural-gas supply will give out before many years, while the cost of coal is likely to be much higher in the future than it was before the war. Today, for reasons appreciated by combustion and power engineers, oil has become a factor fully as important as coal, and, as the economic possibilities of liquid fuel become more widely appreciated, it is likely to become of even greater importance.

THE COMMERCIAL PLANT

Outside of Scotland, the works constructed up to date to undertake the retorting of oil-yielding shales, while fairly numerous, have been relatively small. The limited capacity of these works has been fatal to their commercial success. A commercial retort plant must be of a capacity sufficient to warrant the employment of and the expenditure upon:

1. The necessary technical staff.
2. Machinery of a capacity that will permit of economy of operation.
3. Labor-saving devices.
4. Railway sidings, roads, pipe lines, tank cars and vessels, with their several necessary auxiliaries.

The overhead charges in a works of small output, retorting lean shale, would probably eat up all the profit. This is no new problem in the mining industry. Mineral deposits that are lean must of necessity be mined and treated in a large way, and when so handled have often been proved to be more profitable than richer deposits.

It is fortunate that in the oil-shale industry the underlying chemical principles that govern the retorting of the shale have been established and proved years ago. Today all that remains to be determined, besides the more perfect elucidation of some of those principles, is the most economic application of those principles under the local conditions existing. The Scotch operators fought this question out in Scotland over twenty years ago and devised retorts and methods that suited their special local conditions. Unfortunately the local conditions that once existed in Scotland no longer exist there in their entirety, and are not duplicated on the continent of America.

During the last twenty years many and very important advances have been made in the science and art of combustion, in the conservation of heat and in the production of power and heat; also in the conveying and crushing of ores and similar raw material, in the pumping, softening and filtration of water and in labor-saving machinery generally. Moreover, the laws that govern aggregates are better understood, and during recent years notable advances have been made in the production and in the use of measuring, indicating and recording instruments to measure the flow, temperature and quality of gases, etc., which make possible the refinement of processes not possible when these processes

are directed by rule-of-thumb methods. These advances have made possible economies hitherto unthought of. Some of these improvements have been adopted in part in Scotland, but the majority have not been adopted, as this would have entailed an almost complete rebuilding of the several plants.

PLAN OF A COMMERCIAL PLANT

A commercial retort plant should be planned so as to be:

1. Condensed into an area as small as possible without being congested.
2. Fire-resisting and fool-proof.
3. Capable of continuous operation for a long period.
4. Not requiring frequent attention for small repairs.
5. Should require an irreducible minimum of manual labor.
6. Also the minimum consumption of heat, power and water.

GOOD ENGINEERING WORK ESSENTIAL

These requirements indicate that it is not so much the services of an expert chemist, whether for research or for planning, that are called for, but the services of chemical, combustion, power and mechanical engineers. It is with no desire to belittle the work that can be done, and, indeed, which it is hoped will be done by the research chemist toward the elucidation of certain chemical reactions which at present are not fully understood and other and similar details about which reliable information would be of immense help, but it would appear to be very necessary to point out that the problems that surround the construction of a commercial retort plant are not of a character that a research chemist, and a research chemist alone, can best solve.

The retort plant described in this article is the result of six years' constant development work. It is based upon the employment of chemical principles accepted by the Scotch operators, but the application of these principles has been made to conform to modern practice. This application has been carefully scrutinized and has been approved by chemists expert in gases. The writer has for thirty years made power production a study, having designed and constructed the first hydro-electric power plant operated in Canada. In planning that power plant new improvements were made that since have become standard. The economical production and transmission of power is a science, and the application of this science is influenced to a greater extent than is usually appreciated by the varying factors of local conditions, hence experience is of unusual importance, and the use of theory unattended with experience may result in trouble. As local conditions generally vary within wide limits, it is necessary to plan those parts most affected so that modifications may be made without disturbing the plant as a whole.

PLANS AND LAYOUT OF PLANT

The plant, as illustrated in Fig. 1, is designed to retort 2,000 tons of shale each twenty-four hours. The process commences with the crusher house. The shale is assembled in the works, as shown in the drawing, by the use of an aerial conveyor, such method of assembling possessing certain advantages when used under the conditions usually found in Canada. Such alterations as are necessary to make the crusher department suitable to operate in connection with any other system of assembling can easily be made, as such alterations will

FIG. 1. FLOOR PLANS OF PLANT

be simply matters of detail. The byproduct departments are not shown, their consideration being left for another article. The plan of works exhibited is so arranged that a byproduct plant can be added without disarranging the oil-recovery plant proper.

The crusher plant consists of a coarse crusher, a fine crusher, two screens to remove the "fines" and to return the oversize to the crushers, and a magnetic roller to remove "tramp iron."

The fine-crushed shale is elevated to a shale bin of large capacity located on the top or fourth floor. From this bin the shale is conveyed into and through driers, and from the driers passes through special screens to obtain the removal of the last of the fines, and then is

the shale into each chamber in a constant dribble. The feeder is so designed that the top of the shale in each chamber assumes the shape of a pile with two long sides or slopes, thereby presenting the greatest possible surface to the action of the preheated gases with which the space unoccupied by the shale is kept filled.

RETORTING CHAMBERS

Each chamber of the double retort is rectangular in shape at the feed end. The two chambers of each double retort combine to form one chamber at the discharge end, where are located two discharge rollers, which by rotating keep the charge of shale in constant movement, passing down and through the chambers.

FIG. 2. CROSS-SECTION OF RETORT CHAMBERS

conveyed into the feed bins, situated over each bench of retorts. Under certain local conditions these driers may be dispensed with. The driers are heated by the waste products of combustion of the steam boilers after those products have yielded the major part of their contained heat during their passage through the gas preheater. The objective of these driers is to enable the shale to be passed into the retorts, at all times of the year, possessing a similar physical condition. From the shale bins over the retorts the shale is passed into each of the two chambers of the four double retorts (four double retorts form a bench of retorts) by special but very simply constructed feeders. These feeders pass

The chambers are so designed that this movement is constant and is not subject to obstruction. The heat required to secure the eduction of the volatile contents is supplied by the admission of preheated gases, the product of a previous operation. These gases are admitted into each chamber at several points, two of which are located at the feed end of the chamber. The volume of these gases can be regulated. It is claimed that not only do these preheated gases heat the shale to the necessary temperatures for eduction but that they:

1. Act as a carrier for the oil vapors formed by pyrolysis.

2. Act as a diluent, lowering considerably the vapor pressures and temperatures required for eduction.

The gases and oil vapors are removed from the chambers at several points through apertures specially designed, so that they will not become clogged through the accumulation of deposits, which deposits can be conveniently and quickly removed as formed.

The light-oil-vapor-gas mixture comes over first, and the vapors are condensed by being passed through water-cooled condensers. The heavy-oil vapors are removed and condensed separately. The fluidity of both these gas-vapor mixtures is greatly increased by the thinning action of the gases used for heating the shale. The presence of these gases also mitigates, if it does not altogether prevent, certain troubles that at times are likely to occur in the condensers. The partial fractionation of the light-oil vapors from the heavy-oil vapors also makes possible economies in the topping of the light oils and the economic production of the highest grade of fuel oil.

The water used for condensing the light-oil vapors is used afterward in the heavy-oil vapor condensers, from which it is delivered at a temperature sufficiently high to permit its being fed directly to the boilers.

The retort chambers are fabricated of steel plates. The bench of retorts is inclosed on all four sides by two walls of steel plates, placed some inches apart, the inner plates being welded together so that they are gas-leak-proof. The space between the two rows of plates is filled with heat-insulating material such as kieselguhr.

The division plates that form the several chambers are fastened to the inner of the two plates that form the walls of the bench. As none of these plates are subjected to a critical temperature, it is evident that these parts of the retorts will last for many years. It is also evident that the shale retorted in these chambers, subjected as it is to a regulated heat, every piece of shale being also subjected to the same temperature, will, however rich in kerogen the shale may be, never become burned on to the sides of the retort and thus cause "bridging" of the shale within the retort, and it is also certain that none of the educed gases are likely to be cracked.

COOLING CHAMBER, CONDENSERS AND SCRUBBERS

After being removed from the retort the spent shale is passed into a cooling chamber. When passing from the rollers into this chamber the spent shale is deflected toward the walls of the chamber. These walls are constructed of steel chambers, which are cooled by water. When certain qualities of shales are retorted these tanks can be used to generate low-pressure steam, which as generated is passed into and among the spent shale. The cooled spent shale is removed from the cooling chamber and by the use of suitable conveyors is transported to the byproduct plant, where it is treated specially to recover the maximum yield of ammonia at the lowest cost.

The oil vapor condensers are located on the third floor close to the retorts the vapors from which are to be condensed. Each double retort has two condensers, one for the light-oil vapors and the other for the heavy-oil vapors, the pipes connecting each condensor with its retort being each less than 10 ft. in length. The fixed gases pass into main pipes and are exhausted into gas washers, one for the purpose of recovering the non-condensed gasoline and the other to recover any ammonia that may have been carried away with the gases. From the latter washer the gases pass to gas

holders, from which supplies are drawn to provide gas fuel for the boilers and gas to be heated in the preheater. It is arranged that when in regular operation there shall be burned under the boiler just enough of the gas to maintain a constant quantity of gas stored in the holders.

GAS CYCLE

The steam is generated in vertical water tube boilers of special construction supplied with gas burners of suitable design. The gas preheaters are so constructed that they can be operated constantly for long periods of time and at the greatest efficiency. By the arrangements provided the efficiency obtained from the fuel gas burned will be very high.

The gas cycle is as follows:

1. Gas holder to steam boiler.
2. Steam boiler to gas preheater.
3. Gas preheater to driers.
4. Driers to byproduct recovery or to the air.
11. Gas holder to gas preheater.
22. Gas preheater to retorts.
33. Retorts to condensers.
44. Condensers to exhausters and washers.
55. Washers to gas holders.

POWER DISTRIBUTION

The manner in which the power required is provided is new and is probably unique. By referring to the illustrations it will be noted that no central power house is provided. The power within the works will be generated by individual steam turbines taking steam from the steam boilers at high pressure and passing the condensed steam to the byproduct plant, where it is used in the process of manufacturing. The individual steam turbines used are dust-proof, gas-proof and fool-proof. They will require no more, if not less, attention than do electric motors, will require but small repairs and can be operated continuously for unusually long periods. The total cost is less than that of a central power house with electrical transmission and electric motors and the steam efficiency is higher.

The topping of the light-gas oils is arranged for in the fractionating and refining department. Should it be desired to fractionate and refine the heavy-gas oils an addition for this work would be located directly behind the building in which the light-oil gases are treated. The byproduct department in which the spent shale would be treated for the recovery of nitrogen and (in a few cases) of potash would be located to the right of the retort building.

FIGURES ON COST

Figures on the cost of operating such a works are not usually a criterion of much importance, especially as there are very many different methods of stating such costs. The writer has preferred to adapt a method used for many years in other industries, in which the cost of wages in each department is given separately, while the repairs, depreciation and overhead are given separately but as affecting the whole manufacture. As wages differ greatly, it has been thought reasonable to give the days' labor required calculated at an average rate of \$5 per day, a day usually being one of eight hours' work. With these data it is easy for any one to calculate the costs under such local conditions as may exist. The cost of mining and assembling vary within wide limits, from the low cost of excavating by power-

operated excavators under ideal conditions to deep mining. Such costs may vary from 25c. per ton up to and over \$2 per ton.

Crushing.....	10 men at \$5 per day...	\$50, or 2.50c. per ton
Retorts.....	15 men at 5 per day...	75, or 3.75c. per ton
Power.....	9 men at 5 per day...	45, or 2.25c. per ton
Spent-shale.....	6 men at 5 per day...	30, or 1.50c. per ton
Warehouse.....	11 men at 5 per day...	55, or 2.75c. per ton

Total wages.. 51 men at \$5 per day.... \$255, or 12.75c. per ton

Salaries, including foremen, chemists and management, \$1,120 per week.....	8.00c. per ton
Repairs.....	5.00c. per ton
Taxes, insurance and sundries.....	5.00c. per ton
Depreciation.....	15.00c. per ton
Bond interest.....	15.00c. per ton

Total..... 60.75c. per ton

The foremen should be expert artisans, expert in their several trades, and would thus be competent to attend to any small or minor repairs requiring attention.

It is very evident that a well-designed and well-constructed plant can be operated at a low figure per ton if of commercial size. The cost per ton, excluding depreciation and bond interest, certainly need not exceed 35c. per ton, and where wages are paid at a low rate need not exceed 25c. per ton.

Every important section of the plant is provided with recording thermometers, gages and meters, so that the management can ascertain at a glance how everything is operating. The results obtained from each and every double retort can be accurately ascertained.

Oil Seeds in India

In a recent letter from Trade Commissioner Batchelder he states that in normal years India produces well over 5,000,000 tons of oil seeds, worth about £50,000,000, one-third of which is usually exported. No other country produces such a variety, which includes cotton seed, rape seed, peanuts, sesame seed, mowra seed, poppy seed, niger seed, linseed and castor seed, as well as copra. Linseed, niger seed and poppy seed were formerly used in paints and varnishes as liquid drying oils, and rape seed was employed for industrial purposes, but linseed and rape seed can be refined for the production of margarine, and much rape seed is being used for this purpose on the Continent of Europe. Copra and mowra yield solid fats, while liquid non-drying oils are expressed from cotton, sesame, rape and castor seed, and from peanuts. India furnishes 98 per cent of the castor seed of the world, the oil from which is considered the best lubricant for airplane engines, and also supplies 100 per cent of the mowra, 100 per cent of the niger, 65 per cent of the rape and 76 per cent of the poppy seeds of the world.

Production of Coquito Nuts in Mexico

A recent report from Consul McConnico, Guadalajara, Mexico, states that the coquito palm grows abundantly in the States of Colima, Jalisco, Nayarit and Sinaloa, and that quite an industry has been established in gathering and preparing the small oil-bearing nuts for the market. The estimated annual production of these nuts in the district referred to above is 5,000 tons, valued at prices varying from \$150 to \$250 per ton. Ten years ago, before the value of the nut was really appreciated, the price did not exceed \$40 per ton. Soap manufacturers of Guadalajara and Mexico prize the nuts very highly because of the oily substances derived from them and consume practically the entire production in the manufacture of soap.

The Dimensional Limitation of Successive Heat-Treatments of Carbon Steel

By W. P. WOOD

WHILE concerned with the metallurgical inspection of aircraft engine parts, the following situation came many times to the writer's attention: Forged alloy steel parts, such as connecting rods, came from the heat-treating department to be inspected. The length and other dimensions were checked upon suitable gage blocks and the Brinell hardness was taken. Several of the pieces would be acceptable from the standpoint of dimensions, but would be too hard or too soft. These would be returned to be heat-treated a second time. This procedure might be repeated three or four times upon the same pieces. It was noted that after one or two such successive heat-treatments many of the pieces would have to be rejected on account of failure to fit the gage blocks; in other words, they had shrunk during the heat-treatments.

It seemed that if some information were available concerning the causes and amount of this shrinkage, much time and trouble might be saved. With this thought in mind, the present investigation was started.

Through some rather rough preliminary experiments it was demonstrated that this shrinkage is much more marked in some alloy steels than in carbon steels, but it was deemed best to study the carbon steels first, since the phenomena of their structure and treatment have been more thoroughly demonstrated.

PROCEDURE

Steels of the following carbon content were used: 0.11, 0.32, 0.44, 0.55, 0.64, 0.74, 0.82, 0.99 and 1.14 per cent. Manganese was in the neighborhood of 0.50 per cent and sulphur and phosphorus were both 0.05 per cent or below. Uniform samples 1 cm. square and 10 cm. long were machined from the annealed bar stock. Enough samples were prepared so that several checks could be run.

The length of each sample was carefully measured in a micrometer, the design and operation of which may readily be understood from the accompanying illustration Fig. 1. In making all measurements, the samples were always placed in the micrometer in the same position. The micrometer was frequently checked with a standard 10-cm. block.

FIG. 1. MICROMETER AND FIXTURE FOR LENGTH

It was felt that more comparable results would be obtained if all samples were subjected to the same heat-treatment. The treatment selected was a hardening quench in oil from 900 deg. C., followed by a draw at 600 deg. C. The high drawing temperature was used in order to bring to a maximum all the possible effects which the draw might produce.

A Hoskins muffle furnace was used and a reducing atmosphere maintained by keeping a layer of charcoal about an inch thick over the floor of the furnace. Temperatures were measured by means of a millivoltmeter and a platinum thermocouple which was protected from the reducing atmosphere of the furnace by being inclosed in a fused silica tube. The samples were supported upon horizontal chromel wires and were placed parallel and close to thermocouple. After temperature had been reached, the pieces were allowed to soak for twenty minutes before removal from the furnace. After each hardening and drawing operation the length of the pieces was again measured. Almost no oxidation of the pieces was noted, although each had more or less "oil scale" upon it which was readily scraped off by a slight pressure with the blade of a knife or the finger nail.

Each sample was given three successive heat-treatments, a complete heat-treatment being the hardening quench and draw.

RESULTS

The results are presented in the accompanying graph Fig. 2, representing the shrinkage due to the successive heat-treatments, plotted against carbon content. The zero line is placed in such a position that shrinkage may

FIG. 2. CHANGE IN LENGTH AFTER REPEATED HEAT-TREATMENT

be plotted as a negative and expansion as a positive quantity. The ordinates represent percentage of the original length of the pieces, and the abscissæ represent increasing carbon content.

It will be noted that as the carbon content increases the shrinkage after hardening and drawing decreases. This condition leads one to the conclusion that at least two opposing agencies are influencing the changes in length of the steel.

Considerable light is thrown upon this subject by the work of J. H. Andrew¹ and others in a paper presented before the British Iron and Steel Institute at the May, 1920, meeting. These authors demonstrate by a set of skillfully prepared curves that as carbon steels are slowly heated to 1,000 deg. C. two opposing influences affect the steels—namely, (a) The change from alpha to gamma iron, which is in general of the nature of a contraction, and (b) the solution of carbide, which causes an expansion. As the per cent of carbon

increases, this so called "carbide expansion" increases. In steels carrying less than 0.70 per cent C the expansion is completed in the critical range. In steels carrying more than 0.70 per cent carbon this expansion continues above the critical range. It is concluded by the authors that this continued expansion is not altogether due to solution of carbides, but is continued by the dissociation of carbides in solution.

In the light of what has been said in the preceding paragraph, it may readily be perceived why high-carbon steels exhibit less change after hardening than low-carbon steels.

A glance at Fig. 2 reveals the fact that after the first complete heat-treatment the hypo-eutectoid steels were shorter than they were in the annealed state. The eutectoid steels had not changed much in length and the hypereutectoid steels showed slight dilatation. This condition was one that seemed logical when all of the circumstances were considered.

When a quenched steel is drawn one may presumably conclude that a reversal of all the effects occurring when the piece was first heated will tend to take place. In those steels which carry larger amounts of carbon and have undergone greater expansion we would not expect to find as great an amount of shrinkage relative to original length after a drawing operation.

Two possible reasons occur to the writer in explanation of the observed fact that the hypo-eutectoid steels were shorter after heat-treatment than in the original annealed state. One lies in the possibility that the cooling after annealing did not give as much time for the reversal of the "carbide expansion" as did the draw following the hardening quench. If this were true, the annealed pieces were in a slightly expanded condition when measured.

The second possibility lies in the more rapid contraction of the outer skin of a piece of steel when quenched. J. E. Stead² has mentioned an interesting instance of this in the case of a cylinder of steel which was subjected to many repeated quenchings. After a time the cylinder actually began to assume the shape of a sphere due to the more vigorous contraction of the outer portions of the piece. The length of the cylinder thus tended to decrease.

As a result of the second and third heat-treatments a rather uniform shrinkage in all the steels was noted, not so marked, however, in the case of the eutectoid and hypereutectoid steels. Here the most feasible explanation seemed to be the greater contraction of the outer portions of the specimen of steel during a quench as mentioned in the preceding paragraph.

In conclusion it may be said that the effect of heat-treatment upon the length of carbon steel sections is the result of three influences—the allotropic change in the iron, the solution and dissociation of the carbides and the more rapid contraction of the outer portions of steel objects upon quenching. The net result upon the length of the piece is the algebraic sum of changes in length caused by these three factors.

The hypo-eutectoid steels appear to shrink more rapidly than the others, and thus it would not seem advisable to repeat heat-treatments as often upon these steels as might be possible with precisely machined eutectoid and hypereutectoid steels.

Manufacture of Synthetic Ammonia at Oppau, Germany*—II

Catalysis of the Nitrogen-Hydrogen Mixture—Description of the Catalyzing Plant—Extraction of the Ammonia Formed—Description of the Ammonia Oxidation Plant and Its Operation—Description of the Absorption of the Nitrous Vapors Plant and Its Operation

THE research work of Le Chatelier and Haber has shown that the union of nitrogen with hydrogen is facilitated by an increase in pressure, whereas the increase in temperature lowers the proportion of the ammonia formed but increases the velocity of the reaction. The theoretical maximum of ammonia which can be obtained at 600 deg. C. under a pressure of 200 atm. is from 8 to 9 per cent. It is therefore necessary to absorb the ammonia as fast as it is formed while maintaining a continuous circulation of the gas. The Badische Anilin- und Soda-Fabrik accomplishes this by the use of water instead of by liquefaction of the ammonia, which proved to be costly and at the same time does not insure complete removal of the ammonia formed and also forms obstructions when the temperature falls below the melting point of ammonia. By the use of water as ammonia absorber some water vapor is introduced in the circuit and this eliminates the use of some catalyzers, but it has been proved that this moisture is practically without effect on the efficiency of catalyzers with iron as base.

The destructive action of the hydrogen on the walls of its recipients when the temperature is above 450 deg. C. and at high pressure has caused a series of difficulties and even accidents. It was therefore necessary to use special means for the manufacture of catalyzing apparatus. It would seem that under the above conditions of temperature and pressure the hydrogen diffuses through the metal and combines with the carbon of the steel, giving methane, thus producing blow-holes of appreciable sizes which weaken enormously the resistance of the metal.

DESCRIPTION OF THE CATALYZING PLANT

The Oppau works has two catalyzing plants. The most recent one consists of fifteen separate chambers (Fig. 8) situated in one building, each having a catalyzer A , with its heat exchangers E, E' . The roofing is very light so as to minimize the damage in case of an explosion of the apparatus. A thick wall separates the chambers from the compartment containing a battery of ten circulating pumps P of a total power of 4,000 hp. driven by steam engines M , and, superposed at different levels, twenty-four dissolving tanks, eight coolers K and separators d_1, d_2, d_3 .

The catalyzing apparatus (Figs. 9 and 10) is formed of a steel tube *A*, 12 m. high and 1.10 m. exterior diameter. It ends at each extremity by a flange and is closed by a steel cap *B* fixed with 9-cm. diameter bolts. The cap at the bottom is a truncated cone (16 deg.) which fits into a similar form at the extremity of the tube and is driven into its final position by a hydraulic press. The tube *A*, of 12 cm. wall thickness, has a series of holes from 1 to 5 mm. diameter spaced at regular intervals which serve probably for the escape of the diffused

hydrogen. It is lined with a similar tube *C* (Fig. 11) of soft steel about 2 cm. thick, whose extremities are hammered into the conical part and then the cap is fixed. A concentric steel tube *D* is separated from the tube *C* by a space of 1 to 2 cm. and kept in place by a series of wedges. It is through this empty space between the tubes *C* and *D* that the nitrogen required to counteract the diffusion of the hydrogen is supplied. The tube *D* is lined with a heavy refractory wall *E* formed of superposed cylinders, and finally the inner iron tube *F*, of heavy walls, which contains the catalytic mass. This is the constitution of the upper part only; the lower part of the apparatus constitutes a tubular heat regenerator.

The catalyzer is surrounded by an insulating envelope, leaving between them a small annular space in which cold air may circulate.

The two heat exchangers G_1 and G_2 (Fig. 9) placed near the catalyzers are 8 m. high, 0.90 m. exterior diameter and contain each from 130 to 140 tubes.

Each apparatus comprises also a circulating pump of 0.6-m. stroke, 0.4-m. cylinder diameter driven by a 750-hp. steam engine.

At the outlet of the regenerators the catalyzed gases are brought to the ordinary temperature by eight cool-

FIG. 8. SCHEMATIC ARRANGEMENT FOR THE CATALYSIS
OF $N + H_2$

ers K (Fig. 8), each one being formed of twelve to sixteen series of five tubes 7 m. long, 7 cm. diameter, connected in parallel to parallelepipedic collectors of 12-cm. sides, the whole being inclosed in a sheet-iron vat in which circulates a rapid stream of cold water. The condensed water is collected in horizontal cylinders J_1 . From the coolers the gases enter dissolving columns, each of which consists of three vats C_1, C_2, C_3 (Fig. 8) with pipe coils. These vats are superposed and spaced from 6 to 7 m. apart. They are connected to the vertical cylinders d_1, d_2, d_3 , in which the liquid separates from the gas. The capacity of these separators is 200 liters.

The vats are 1.8 m. high, 3.5 m. diameter and contain twelve concentric steel coils of 5 cm. diameter of the same length and whose corresponding extremities are

24, No. 7, p. 305, Feb. 16, 1921.

fixed to a manifold, the lower part of which is connected to a separator. The vat contains the cooling water. The dissolving water, compressed to 200 atm., is divided as uniformly as possible for each of the coils. Indicators permit observation of the liquid stream entering each coil. This water circulates from vat to vat, starting at the top, the separator of each vat being connected to the top of the coil in the vat immediately below. The solution leaving the last separator enters the receivers J_2 .

These receivers are provided with indicators which show when the level of the liquid reaches the maximum. A series of valves permits the emptying of the liquid with successive expansions into closed reservoirs of about 20-cu.m. capacity, these reservoirs being designed to resist internal pressures of from 2 to 3 kg. Nitrogen and hydrogen, which dissolve along with the ammonia, are recovered from these reservoirs and sent back to the gas holder for the mixture $N_2 + H_2 + CO_2$.

The operations are controlled by a series of measur-

ing apparatus—namely, thermocouples, measuring burettes, registering apparatus for hydrogen content (based on the velocity of diffusion of the gas through a very small orifice), registering manometers, Bosch balances and registering apparatus for the velocity of the gaseous currents.

FIG. 11. DETAIL OF TOP OF CATALYZER

and hydrogen. The gases of the blowpipe are injected at a pressure of 200 atm. The ignition is produced by a platinum wire maintained at red heat to produce the union of oxygen and hydrogen in case the first of these gases should accidentally reach the blowpipe.

About 18,000 cu.m. of the gaseous mixture passes each furnace per hour, producing about 20 g. of ammonia per twenty-four hours.

The difference in pressure of the gas between the inlet and outlet from the circulating pumps is generally between 4 and 5 atm. and was never higher than 15 atm. The temperature of the gases at the outlet from the heat regenerators is between 140 and 150 deg. C. The ammoniacal solution contains about 25 per cent ammonia.

EXTRACTION OF THE AMMONIA

The ammoniacal solution is pumped by a centrifugal pump through a meter and into a 2,500-cu.m. reservoir. From the reservoir the liquor enters at *a* (Fig. 12) the heat exchanger *R*, thence through *b* to the top of the tower *A*. This tower is 2 m. diameter, 10 m. high and well insulated. Steam is injected at the lower part of the tower at *c*. The liberated gas and the steam pass through a cooler located on top of the tower. This cooler contains 525 horizontal tubes of 8 mm. diameter through which cold water circulates. The ammonia escapes through pipe *d* into a collector *D* which is common to all the twenty-four towers in the building and thence to a 12,000-cu.m. gas holder which contains water covered with a layer of oil to retard the saturation with ammonia. The water of solution and the condensed vapor, which now contains only less than 0.0005 ammonia, leaves through *f* at the lower part of the tower and passes through the regenerator *R*, whence a part goes through *g* to the dissolving apparatus and the other part to the boilers.

DESCRIPTION OF THE AMMONIA OXIDATION PLANT, AND ITS OPERATION

The Badische Anilin- und Soda-Fabrik oxidizes the ammonia by a catalytic mass which appears to be a mixture of oxides of iron, manganese and chromium agglomerated with bismuth chloride.

There are two oxidation buildings. The newer one

consists of three groups of two Rateau ventilators direct-connected to a 200-hp. steam turbine. The ventilators are of different sizes. The smaller ventilator of each of the groups circulates 36.8 cu.m. ammonia per minute, the larger ventilator brings in 46.6 cu.m. filtered air per minute. The three groups send their gases into a 2-m. diameter 10-m. long horizontal cylinder located underground and in which the mixture takes place. From this reservoir the gas mixture arrives through pipings *a* (Fig. 13) to eight regenerators and thence to sixteen oxidation furnaces *B* placed in two rows along the building. The oxidized gases enter the tubes of eight waste heat boilers (not shown in Fig. 12). A series of sixteen gas furnaces *C* serve for the heating of the oxidation furnaces.

The catalyzing apparatus grouped by twos consist of cylinders 3.5 m. external diameter and 5.5 m. high. They are well insulated. The upper part of the cylinder is closed by a brick top provided with a central opening *c* for the escape of the heating gas. A brick partition divides the chamber into two nearly equal parts. This partition is plane and horizontal at the top part and spherical at the bottom part. It is provided with 15-mm. holes spaced at about 8 cm. centerlines. These holes are slightly closed. The contact mass in sizes of 5 to 8 mm. is placed over this partition in a uniform layer of about 5-cm. thickness. The oxidized gases after leav-

FIG. 12. SCHEMATIC ARRANGEMENT OF EXTRACTION OF AMMONIA

desired composition, the required amount of air or ammonia is added.

Each furnace oxidizes about four tons of ammonia per day with an efficiency of 80 per cent. The duration of contact is about one-half second.

At the Oppau plant from 180 to 200 tons of ammonia could be oxidized per day, but it would seem that at present only eighty tons per day is oxidized.

ABSORPTION OF NITROUS VAPORS

The nitrous vapors obtained by oxidation of the ammonia are absorbed by water, giving a 50 per cent solution of nitric acid, or by a sodium carbonate solution, giving a mixture of nitrate and nitrite of sodium.

The plant contains five stone or brick towers (I, II, III, IV and V, Fig. 14) and two brick columns (VI and VII) lined outside with sheet iron.

The gases arrive in tower I. This tower has a decag-

FIG. 14. SCHEMATIC ARRANGEMENT FOR THE ABSORPTION OF NITROUS VAPORS

onal section 5 m. in diameter and 15 m. high. Towers II and III are cylindrical, 7 m. in diameter and 20 m. high; towers IV and V have a decagonal section 6 m. in diameter and 20 m. high. All these towers are lined inside with 20-cm. thick acid-proof layers. The two columns VI and VII are used for the circulation of soda solution. The towers and the columns are filled with Raschig rings and stand on foundations 5 ft. high.

There are three towers I, to which correspond six reservoirs (1 to 6) 2.5 m. in diameter and 4 m. high. Between the towers II and III, IV and V there are also six reservoirs (7 to 12 and 13 to 18). These twelve reservoirs are 3.5 m. in diameter and 4 m. high. All the reservoirs are of brick, tarred inside and connected by stoneware piping. In the piping of the last four towers there are stoneware valves for sampling the liquors. All the pipes leading to towers of the same order are connected to a horizontal manifold. A stoneware overflow pipe is provided for each reservoir and the overflow escapes through underground channels.

The circulation of the acids is maintained by centrifugal pumps made of a 15 to 18 per cent Si pig iron called Elianite, and which are driven by electric motors.

There are two groups of two pumps A and B (Fig. 14) for the three towers I, a group of four pumps C and one group of two pumps D for the towers II and III, a group of four pumps E and one group of two pumps F for the towers IV and V.

The circulation of the sodium carbonate and nitrate solutions is made by two groups of two pumps driven by 110-kw. motors.

Other pumps serve for the circulation of cold water, warm water or soda solutions to the top of tower V.

The solution of filtered nitrates is sent to the reservoirs by six pumps. Two pumps collect the solutions of nitrate and carbonate spilled on the floor of the build-

FIG. 13. SCHEMATIC ARRANGEMENT OF THE INSTALLATIONS FOR THE CATALYTIC OXIDATION OF AMMONIA

ing the regenerators are received into condensation towers.

The operation is kept under control by:

Peep-holes which permit observation of the catalytic mass, which is to be maintained at red heat.

Thermocouples giving the temperatures at different points (inlet and outlet of regenerators, inlet to boilers.)

Recording velocity indicators of the gaseous currents and manometers.

Gas-testing apparatus at inlet and outlet.

When the temperature tends to exceed the desired value a bypass valve brings in a part of gas which does not pass through the heat exchanger. This addition is made through piping *e*. If the mixture has not the

ings and send it to the reservoirs. A ventilator driven by a 130-kw. motor is placed on the outlet piping for gases, and two others serve to send air into the pipings bringing in the nitrous vapors.

All these pumps and ventilators absorb a total of 2,000 kw.

The acid collected at the bottom of the towers I, II and III is cooled in refrigerators *R*. These refrigerators are composed of thirty-six horizontal tubes connected in three groups and cooled by cold water sprays.

The gas arriving at the lower part of the towers I at *a* leaves at the top, enters the towers II at the lower part, and so on up to towers IV, whence the gases enter the towers V at the upper part.

The pipings of the towers III are connected to a single horizontal pipe which permits to bypass any one tower of the last three groups.

In the soda columns the gases enter at the lower part and leave at the upper part.

In the towers I, in which the temperature is about 50 deg. C., the acid obtained is of 35 per cent concentration; in the towers II the temperature is about 40 deg. C. and the acid is of 40 to 50 per cent concentration; in the towers III the temperature is 35 deg. and the acid is of 25 per cent concentration. The towers IV and V are at a temperature approaching the atmospheric temperature and they contain a diluted acid which is used for the production of sodium nitrate. Eighty per cent of the oxides of nitrogen is transformed into acid, 15 to 16 per cent into nitrates and 4 to 5 per cent is lost. The daily production of nitric acid would be about 264 tons.

Sulphuric acid is used for the concentration of the nitric acid in six cylindrical columns 10 m. high. These columns are steam heated. Two of the columns are of stone; the others, of more recent construction, are built of sectional Elianite tubes 75 cm. long, 1 m. in diameter, 4 cm. thick, connected by conical joints. These columns are provided with loosely laid Raschig rings. Sulphuric acid enters at the top of the column, nitric acid is supplied by two tubes entering the column respectively at 2 m. and 3 m. from the top of the column. Steam enters at the bottom in the center. The concentrated nitric acid vapors leave at the top of the column through Elianite pipes and enter the water-spray-cooled refrigerators. The condensed acid is collected in a reservoir. The non-condensed vapors are led by stoneware pipes to the nitrification towers described above.

The sulphuric acid is denitrated in columns analogous to those for concentration but only 6 m. high.

The denitrated acid passes through tubular coolers, and enters two lead-lined vats 4 m. high and 5 m. in diameter provided with seven cooling coils and thence to eight Kessler concentration apparatus 4.5 m. long, 3 m. wide and 1 m. high. These are heated with Kraftgas.

The nitration of sodium carbonate takes place principally in vats 3 m. in diameter, 2.5 m. deep, lined inside with brick and provided with wooden agitators. The carbonate solution used in these vats comes from a special dissolving building or from the Solvay soda plant. The acid vapors are brought in by three pipes.

The nitrous and nitric vapors liberated in the reaction are led to the bottom of column VI. The nitrate-nitrite solution after filtration is collected in three reservoirs 10 m. high and 3.5 m. in diameter.

(Part III, the last, will be published in a subsequent issue.)

Condition of the German Sugar Industry at Close of 1920

Germany is confronted with the problem of increasing its sugar production to meet domestic needs, reports Howard W. Adams, representative of the Department of Commerce, Berlin. In the sugar-production year 1919-20 there was a total of 269 sugar-beet mills in operation in Germany, as against 307 for 1918-19. Since the latter period thirty of the 307 mills referred to passed out of German jurisdiction along with those territories transferred from Germany under the treaty of Versailles.

SUGAR-BEET PRODUCTION IN 1919-20 SHOWS LOWEST AVERAGE FOR MANY YEARS

The sugar-beet production in Germany during the period 1919-20 attained an average of only 19 metric tons per hectare (hectare = 2.47 acres), the lowest average for many years. This diminished production is ascribed in part to the bad weather conditions existing at the time of planting and to the inadequate cultivation of the crops, due to the lack of labor and strikes. The first examination of the plants disclosed the fact that the average weight of the root was only 88 g., as compared with the preceding year's weight of 173 g., and a sugar content of 11.7 per cent, as against 12.4 per cent for the preceding year. The final examination of the plants showed a somewhat increased average sugar content, but considerably smaller beets—namely, 342 g. weight and 20.9 per cent sugar content, as against 504 g. and 19.8 per cent, respectively, for the year previous. Then a further setback to production occurred in the form of frost, which set in just at harvest time and as a result prolonged the work of completing the harvest with an accompanying heavy loss in sugar.

DOMESTIC PRODUCTION INADEQUATE TO GERMANY'S NEEDS

The net sugar production for 1919-20 amounted to a total, in round numbers, of 733,000 tons of raw sugar, as compared with 1,346,000 tons produced in the preceding year. Consequently, the domestic production was inadequate to meet the country's needs, which during the preceding year amounted to about 1,000,000 tons. It therefore became necessary for Germany to import 57,000 tons of sugar, as compared with the 29,000 tons imported during the preceding year. The only thing that saved Germany from a heavier importation during the 1919-20 period was the supply of 216,000 tons which became available from the stocks of the preceding year.

CONDITIONS PROPITIOUS FOR DEVELOPING CULTIVATION AND INCREASING PRODUCTION

At the beginning of the new sugar year Germany finds itself without available stocks of this commodity on hand. There is felt more than ever the pressing need of developing the sugar-beet cultivation and increasing production as far as possible. Conditions appear to be propitious for such a result. The cultivable acreage shows a slight increase—4 per cent—over that of the preceding year, and the fields are reported to be in good condition. The question remains as to whether the sugar mills will receive supplies of coal adequate to their needs and whether strikes among the farm laborers will disturb cultivation.

Safety Methods Applied in the Ryerson Steel-Service Plants

An Outline of the General Organization for Safety Promotion in the Plants and of the Results Leading to Better Relationship Between Management and Workers and to Ultimate Reduction of Plant Operating Costs and Higher Efficiency

THE prevention of accidents is an essential function of modern industrial management. Safety means not only a humanitarian movement, but goes far toward a better relationship between management and workers, and it has a direct influence on the cost of production.

Even though there were no material benefits to be derived from the prevention of accidents, it would still be desirable for industry to put forth a powerful effort in the elimination of hazards. But the practical results of a continuous, concentrated safety campaign are so evident that the work is also well warranted on a basis of dollars and cents.

The Joseph T. Ryerson & Son plants inaugurated intensive safety work six years ago because the management appreciated the opportunity to protect its workers, and the same impulse continues to keep the interest keen. These efforts have had ample reward.

Safety promotion means not merely the showing of bulletins and the soliciting of suggestions. To be really successful, it demands a more vital interest on the part of the entire working force.

ENTHUSIASM ESSENTIAL

The secret of success in safety promotion is the maintenance of eternal interest and enthusiasm. Enthusiasm cannot be instilled satisfactorily by merely forming an organization or by providing a system for handling suggestions. To be enthusiastic, a man first of all must believe in the thing heart and soul. If a workman does not really understand and sympathize with accident prevention, no amount of bulletin boards or "safety sermons" will have any effect on him. He must be sold just as thoroughly as must a purchasing agent when considering a new product. Furthermore, he has got to have the goods delivered to him in the style which he

can understand. This requires many different forms of activities and constant resourcefulness in treating with the individual.

Safety work without organization is as ineffective as in any project without a method of operating. Just as we need a production man to plan the routing of work through our shop, so also do we need a man to be responsible for accident prevention.

Committee meetings are excellent in promoting a general familiarity and team work among the men, but safety meetings that lack real interest are worse than useless.

Talking with each man individually every day is impossible in a large plant, but an efficient substitute can be gained by providing bulletin boards that carry a daily message to the workman. Bulletin boards to

THE FIRST-AID ROOM

talk to workmen must say something, and say it with a punch. No man will take time to pore over a bulletin which is ambiguous, or too lengthy. Snappy and clear cut items on a neat appearing bulletin board never fail to attract attention. The following is an example of such bulletins:

NOTICE

TO ALL MEN SEEKING EMPLOYMENT

If you are unwilling to

THINK "SAFETY"

WORK "SAFELY"

and

BOOST FOR

"SAFETY ALWAYS"

You Should Not Ask For Employment Here

WE HIRE SAFE MEN ONLY

— IF EMPLOYED —

be sure to get a Safety Rule Book at once. You should read it carefully, and in your work abide by all its regulations. You will be expected to read regularly the Safety Bulletins and to promote Safety-Always-Everywhere.

This sign is placed at the entrance of our employment department where all prospective employees are bound to read it.

COMPETITION EFFECTIVE

Among all these essential measures, however, none compares with the use of the competitive spirit. Why not utilize one of the best traits in human nature? It is what causes men to strive for higher goals in every kind of endeavor. In safety work it is just as strong an incentive. Many workmen have been known to treat lightly the consideration of safety when the only incentive was the prevention of accident to themselves. But place those same men in a contest with others, competing for the safety record, and you have a different story. They are eager and watchful. They themselves not only are careful but they are quick to discipline a fellow worker if he fails to play the game.

All the foregoing are intended for the most part to arouse interest, to maintain enthusiasm.

Most of the real constructive steps are taken through the system for receiving suggestions and for making periodical inspections.

A STRONG ORGANIZATION

The first step taken for the elimination of accidents was the creation of an organization that would be responsible for the carrying on of the work. Operating men who are busily engaged in directing the Ryerson steel-service plants have ex-officio positions on the committees, but are not held directly responsible for the carrying on of the campaign. Betterment department men, whose duties in other lines are entirely consulting, are chairman of the various committees and take the initiative in planning innovations and are responsible for the maintenance of continual interest in the work. Each plant has its own officers and full committee so that direct action can be taken on suggestions, and so that

local meetings can be held as frequently as desired. All are, however, co-ordinated by an inter-plant executive committee, the chairman of which is responsible to the vice-president of the company. This committee inaugurates inter-plant contests and makes it possible for the various local plants to make use of the ideas developed by the central committee, as well as by the other plants.

An interesting feature of the Ryerson safety organization is the provision for rotating the workman members of the plant committees. They are selected monthly, and the number of men on each plant committee is so calculated that every man in each plant has his turn at least once a year. Changing the committees once each month brings new energy and interest into the organization. Successful safety work requires inspiration and inspiration from plant men can best be gained by utilizing the greatest number possible.

BULLETIN BOARDS

A few fundamental rules govern the handling of the Ryerson bulletin boards:

1. They are placed in positions about the plant where men—because of necessity or habit—most frequently congregate. Very often the mistake is made of placing the board in an obscure corner of the factory, and then expecting the workman to go to it. Newspapers are sold because aggressive newsboys bring the papers to your very hand. If the daily papers expected their patrons to walk to a central point to secure the morning sheet their sales would fall off appreciably. Likewise with the safety bulletin board. We are selling the workman a daily news sheet on "safety," and we have got to bring it to his attention, and not expect him to take the initiative in hunting it up.

2. One person should be responsible for the placing of bulletins on the board. If there is no such rule in

AN APPEAL TO HOME INSTINCTS

the factory and any one feels free to post whatever seems to him appropriate, the result is the same as would be the appearance of a newspaper which was edited by its entire reportorial staff. The Ryerson bulletin boards are in charge of one individual in each plant, who alone can unlock them and who alone is responsible for their appearance.

3. Interest travels in cycles, and accordingly that which attracts a man one day palls on him the next. Bulletin boards are changed daily, so that every morning

BATTERY OF SHEET SHEARS SHOWING GEAR GUARDS

the worker entering upon his job has before him a fresh thought on safety. Sometimes a very good bulletin can be posted a second time after a lapse of several months. But to allow the bulletin board to remain unchanged for several succeeding days is likely to mar the whole safety program. A man finally concludes that there is nothing to interest him on the board and therefore decides not to bother looking at it again. He has then got to be sold all over again, as far as his interest in reading safety bulletins is concerned, before he becomes what is desired—a habitual daily reader of the safety bulletin board.

4. "What kinds of bulletins do the work?" is a frequent query. Every plant is different, of course, in the type of men employed and accordingly in the language which must be used in pointing out hazards. Years of experience have taught the Ryerson safety organization a few fundamental rules in the preparation of safety bulletins. They should not be long or ambiguous. They should have a definite point. Wherever possible they should be illustrated with a photograph, or a magazine clipping, or with an exhibit such as a broken goggle, a worn-out glove, etc. They should cover subjects which are recognized by the men as directly affecting their own working conditions as far as possible.

An interesting and very effective way of determining the relative value of different types of safety bulletins, as well as of stimulating general interest, is by holding a preference vote. The Ryerson plant safety committee men have posted before them different types of safety bulletins. Arguments for and against the different types are heard from the various members, and a vote is then taken as to the prize bulletin submitted.

SUGGESTIONS ADD INTEREST

One of the most effective ways of stimulating interest in safety work lies in the encouragement of suggestions from the workman. Men take a natural pride in seeing their own suggestions put into effect. The Ryerson safety organization makes it a point to welcome all suggestions and also to put them into effect, if they are at all practical. Many times the interest that is created through the approval of safety suggestions is of even more value than the actual result of the improvement itself.

It has been found that men hesitate to place the suggestion in a box such as is usually provided. Not being able to see whether there are any other suggestions therein or whether or not they are ever removed, their interest will naturally lag. Glass bowls with red lights

in the background have been provided for the receipt of safety suggestions from Ryerson workmen. These bowls are emptied daily, and it has been found that the sight of even one suggestion in the glass bowl has prompted others to present theirs, where otherwise they might have never given the matter a thought.

LIVE SAFETY MEETINGS

The holding of safety meetings is a good deal like the conduct of a political gathering or of any other congregation where it is the object to interest the audience in a specific issue. It is frequently found desirable to include on the program a number of features which, although entirely irrelevant to the subject at hand, have nevertheless an interest which holds the meeting together and arouses enthusiasm. That is why political campaigners like to visit state fairs. The crowd is there to hear and see what really interests them, and incidentally the campaigners get their opportunity.

The safety meeting is advertised in advance. Bulletins posted on the various boards announce perhaps the fact that a fellow workman is billed to talk on "How to Make the Assembling of Sheets Safer." It is suggested in the bulletin that every man ask his foreman for permission to attend the meeting. Of course, it is impossible for every man to be allowed to attend such a meeting, but the object is gained thereby of arousing indirectly an interest in safety by instilling a desire in every workman's mind.

Every man is probably surprised to learn that Bill Jones, his fellow workman, has agreed to stand before them and discuss "Safety." Their curiosity is aroused. They are anxious to know how Bill got the nerve and also whether he can "put it across." The idea of securing a lesson in safety probably never occurs to a single man, because each is far more interested in how Bill Jones is going to deliver.

Nevertheless, in the meeting there is going to be a lesson in safety. That will be assured in advance by those in charge of the meeting. And so, without hardly realizing it, all who attend the gathering will receive a bit of experience or an item of knowledge that will react toward the promotion of safety.

There is a general inclination among all men to dislike being preached to. They do not of their own free

HUGE PLATE SHEAR SHOWING GEAR GUARDS AND CAREFUL METHOD OF PILING STOCK

HIGH-SPEED FRICTION SAW OPERATED WITH SAFEGUARDS AND BY SAFETY RULES

will attend meetings where they suspect that they are going to be "talked to." However, a sermon can be presented indirectly sometimes in the form of a suggestion. And much easier than that can be the presentation of a thought on safety in an indirect manner. Give a man the nucleus of an idea, the foundation on which the thought is based, and he will make the proper decision himself. He likes to do that, and when a man believes he has made his own decision he is jealous of it, he champions it against all odds. That is the ideal condition in which to have the workman's mind in regard to safety.

A man who has made up his own mind that safety is a fine thing is worth ten who believe it simply because they think it is a good policy to do so.

PLANT COMMITTEE MEETINGS

At least once each month each plant committee holds a meeting at which it discusses reports, inspections, suggestions, accidents and other routine occurrences. These are called the routine committee meetings. Also once a month another meeting is held, such as we have described, to be attended by a considerable portion of the plant men and where no routine matter is taken up, where the sole object is inspiration for safety.

When we state that these meetings also result in cooperation, in good fellowship and in an excellent understanding, we merely express the obvious. The main purpose is the promotion of safety, but the byproducts are also very much worth while.

REGULAR AND FREQUENT INSPECTION

The backbone of accident prevention is regular and frequent inspection. Every stock room and piece of equipment in the Ryerson plants is inspected once each week by members of the plant committee. A detailed report on the condition of each item is submitted to the chairman of the committee. This chairman is responsible for seeing that dangerous conditions are remedied through the proper operating channels, and he also makes certain that the members of the committee are sufficiently thorough in their inspection.

PRIZES AND REWARDS

Contests to be successful must be both personal and collective. They must be personal in order to provide an incentive for each individual, and they must be collective in order to insure proper team work.

The plants, although scattered at widely different points, in Chicago, New York, St. Louis, Detroit and Buffalo, are nevertheless tied together by a closely knit organization, and a healthy and friendly rivalry in everything that makes for better service and working conditions. They compete with one another in safety with the same ardor that they show for greater steel tonnages and speed in shipment.

The plant which at the end of six months has the highest percentage standard is considered the prize winner, and every man in that plant, eligible through length of service, receives a reward in cash. Individual workmen in other plants are not neglected, however, if they themselves have a perfect score, even though their plant may fall down. Individuals maintaining perfect records for themselves throughout the contest period also receive a cash reward. It is a fact that a large majority in all plants earn their individual perfect record rewards.

Although the foremen should not be held entirely responsible for the conduct of the safety movement, nevertheless their influence in promoting the work should be clearly recognized. A foreman can be a hindrance to aggressive safety campaigning, even though not actively in opposition, by being merely passive in his enthusiasm. On the other hand, he can give a tremendous impetus to the prevention of accidents.

The foremen are encouraged to aid in every way in promoting safety, and are given a practical incentive for so doing. Every month the foreman whose department is leading in the contest receives a cash prize. Not alone is it the money reward which spurs the foreman to accomplishment in the safety campaign, but the natural desire to maintain his plant in the lead over other plants is an even greater incentive.

VARIOUS SAFEGUARDS

Various safeguards installed in the plants mutely testify to the low accident rate prevalent and to the ever lessening likelihood of workmen becoming injured.

Safeguards are not limited to any one class of machines or conditions. Sometimes the most dangerous appearing machines are the ones which do not require safeguarding as much as other conditions where danger is less obvious. For instance, the condition of floors, ramps and stairways is a common hazard which is very often overlooked, and accidents resulting from slipping and tripping or falling are taken as a matter of course. Safeguarding workmen from accidents of this kind is nevertheless just as important as protecting machinery, because the hazard in most cases is presented to a greater number of men. Safeguarded machines protect few men; safeguarded stairways protect the entire working force.

The Ryerson organization has met the situation by adopting the very best anti-slip material for stairways, ramps and slippery floors.

THE RESULT—SAFE PLANTS

The experience of an organization which for years has conducted an intensive promotion of safety means more perhaps to such a company than do the arguments of the safety campaigners.

It is difficult to determine the decrease in accidents in an organization which is growing and extending as fast as the Ryerson company; however, figuring conservatively from the yearly accident statistics, the accident rate has been reduced 80 per cent and even better is expected.

Legal Notes

BY WELLINGTON GUSTIN

Rights to Trade Mark Between Manufacturer and Distributor

A question of trade mark rights was decided by the Court of Appeals of Maryland in a suit brought by Corkran, Hill & Co., against the A. H. Kuhlemann Co. of Baltimore. The trade mark was known as the "Orange Brand" and had been used by the first-named company for many years covering meat products. In 1910 the company began to sell oleomargarine products, buying such from the Kuhlemann company. It furnished at its own expense the labels for such product, employing the words "Orange Brand," and stated thereon, in obedience to a requirement of the Government, the place where such article was manufactured. No oleomargarine product bearing this trade mark was sold by the Kuhlemann company to any one else. This course of dealing continued down to 1914. From 1914 to 1916 the plaintiff used the trade mark slightly changed, it being the same in design as that registered in the Patent Office in 1908. In 1916 the contract between the parties was more general, in which labels were used showing the Kuhlemann company manufacturer of the "Orange Brand" and Corkran, Hill & Co., as distributors. In this same year the Kuhlemann company, without the knowledge and consent of the other, had registered in its name the "Orange Brand" trade mark for manufacture and sale of oleomargarine. Upon discovery of this proceeding Corkran, Hill & Co. demanded surrender or abandonment of such trade mark, and instituted this suit. The trial court decided against Corkran, Hill & Co.'s claims and dismissed the case, but on appeal the Court of Appeals has reversed the lower court.

It was said to be unnecessary, to entitle the claimant to the use of a trade mark, that it should have been the manufacturer of the article. Neither was it necessary that the trade mark should have been registered to entitle plaintiff, the claimant, to use of trade mark, or to protect the company and its work against infringement.

The facts showed that Corkran, Hill & Co., or its predecessor, designed, adopted and used the "Orange Brand" trade mark, and thereby acquired exclusive right to its use. This right persists unless abandoned or acquiesced in its use by the defendant. The court said an abandonment is the voluntary and intentional disuse or non-use of the trade mark. Such intention may be inferred from circumstances necessarily pointing to an intention to abandon, but an actual intention to give up permanently the use of the trade mark is necessary to constitute an abandonment of it. Mere disuse, though for a considerable period, in the absence of intentional abandonment will not amount to an abandonment, nor will it destroy trade mark rights, unless the mark has ceased to be distinctive and the good will associated with it has passed away, or the mark has become identified with other goods.

Finally, it was said where the manufacturer was permitted to use the trade mark for goods put up for the

distributor, there was no abandonment of the mark by the distributor, nor was the right to use it lost by such distributor on account of its acquiescence in the use by the manufacturer for their mutual benefit.

A permanent injunction therefore was awarded to Corkran, Hill & Co.

Contract to Buy May Not Be Transferred Without Consent of Original Seller

Litigation between the Phosphate Mining Co. and the Atlanta Oil & Fertilizer Co. has occupied the courts for several years over a contract of the latter to accept and pay for phosphate rock mined by the former. The latest decision in the matter is that of the Court of Appeals of Georgia (103 S. E., 873) affirming the trial court. The two questions presented the jury were the "rule of avoidable consequences" and "whether the seller had in fact consented to the transfer of the contract."

It appears that the Atlanta company transferred its purchase contract to the Empire Cotton Oil Co. and contended that because of such transfer it was not liable under the contract.

The court instructed that if the transfer was made to the Empire company and the Phosphate Mining Co. accepted the transfer, the Atlanta company was relieved of further liability but the Empire company would assume such obligation that might arise out of the contract. The Atlanta company would be relieved either by express contract or by implication having notice of the transfer and accepting it. The jury found there was no notice and acceptance of the transfer of the contract by the seller, Phosphate Mining Co.

The action being one for damages for the buyer's breach of written contract to accept and pay for phosphate rock, a charge to the jury, on the issue of damages and the avoidance of consequences, that, if the buyer breached the contract, the seller might recover the difference between the market value and the contract price for the rock, was not erroneous as ignoring the defense by the buyer's transfer of the contract to another company and the seller's duty to minimize the damages after its acceptance of such transfer.

The contract provided:

"Buyers are at liberty to diminish the quantity called for in any year to the extent of not exceeding 10 per cent, provided that the quantity to be taken shall not be less than buyer's consumption, and provided further that notice of such diminished demand be given seller twelve months in advance of such change."

The seller was notified that the buyer had no demand for consumption and had no capacity for consumption after July 1, 1912, and had sold out its plant and transferred its contract to another consumer, the Empire Cotton Oil Co., the purchaser of its plant. The action of the purchaser, and its refusal to take any rock, operated at least to diminish the quantity specified in the contract to the amount of 10 per cent beginning one year after such date. The purchaser of the plant and transfer of the contract notified the seller, Phosphate Mining Co., in writing to decrease the quantity specified in the contract 10 per cent beginning one year from date of that notice, or one year from July 9, 1912.

The points having been determined in favor of the mining company, judgment for it was affirmed.

Polishing Motor for Metal Sections

By CHARLES Y. CLAYTON

While the microscopic study of metals is as a rule most interesting, the preparation of the specimen for study is generally an irksome task. Unless the polishing machines are carefully designed and arranged the task is usually a long one.

The common method now in vogue is to rough-polish

FIG. 1. CAST COPPER; ETCHED WITH $\text{NH}_4\text{OH} + \text{H}_2\text{O}_2$. $\times 100$

on a vertical wheel and to finish on horizontal disks covered with the proper media.

Having experienced considerable trouble with horizontal disks mounted on spindles driven by belts or friction clutches, the writer designed a vertical motor with a rotor shaft sufficiently long for a threaded end to permit affixing a bronze disk.

The motor was made by the Cincinnati Electrical Tool

FIG. 2. DESIGN OF MOTOR

Co. It operates at 3,000 r.p.m. and gives complete satisfaction. Even soft metals can be polished with the proper care, as is shown by Fig. 1, a microphotograph of cast copper polished on this machine.

Fig. 2 shows the design of the motor, horizontal disk and water pan. Fig. 3 is a photograph of the assembled unit.

FIG. 3. ASSEMBLED POLISHING UNIT

Automatic Motor Pump

This is a novel device developed by the Austin Machinery Corporation of Chicago, for pumping and measuring the water discharged into concrete mixers. The importance of proper quantities of water in each batch of concrete mixed is well known, and this device will be welcomed as solving this much discussed problem.

The apparatus consists of a pump, a valve, a timer and pipe with fittings. The pump is driven from the mixer shaft and works continuously. It has a lift of 12 ft. from dead water level to pump or can take water from a hydrant. The two-way valve is opened and closed by means of a cam on the timer, which is in turn controlled by the starting lever. With the valve open, water is discharged to the mixer. When it is closed, water circulates through the return loop in the piping.

The operator opens the valve by throwing the starting lever over to the timing pin. Then he forgets it until the next batch is ready for water. The valve closes itself automatically at the precise moment the predetermined quantity of water has been discharged. The amount required is a matter of indifference, since the device has a range of about 250 per cent from minimum to maximum discharge.

The total equipment weighs less than 200 lb.

AUTOMATIC MOTOR PUMP

Wallace Elected Secretary American Engineering Council

WHEN American Engineering Council of the Federated American Engineering Societies was organized in Washington last November the selection of an executive secretary was deferred until the field could be thoroughly canvassed to discover the man best suited for this important post. Practically three months later, at a meeting of the Executive Board of the Council at Syracuse, N. Y., Feb. 14, the board elected Lawrence Wilkerson Wallace to succeed L. P. Alford, who has been acting secretary since the formation of the Council.

Lawrence Wilkerson Wallace has been one of the most active figures in the Council and from the time it was organized has been its treasurer. As vice-chairman of the Council Mr. Wallace has been directing the work of the committee on elimination of waste in industry, one of the principal committees of the Council, whose scope, following the Syracuse meeting, will be greatly broadened.

Mr. Wallace was born in Austin, Tex., Aug. 5, 1881. He was graduated from the Agricultural and Mechanical College of Texas in 1903 with the degree of B.S. in mechanical engineering. In 1912 he received the degree of M.E. from Purdue University. From 1903 to 1906 he served a special apprenticeship with the Santa Fe Railway Co. at Cleburne, Tex., and was a member of the Purdue faculty during 1906-07, becoming head of the department of railway and industrial management in 1913.

As head of this department he was in charge of instruction pertaining to railway mechanical engineering and industrial engineering and of the research work carried on in the railway laboratories; made extensive research pertaining to locomotive performance through both laboratory and road tests and made an exhaustive study by road and laboratory tests on the possibility of fire from locomotive sparks, which information has been largely used in fire cases. His investigations have also covered tests of brake beams, truck side frames, truck bolsters and many other features of car and locomotive construction.

After leaving the university Mr. Wallace became assistant general manager of the Diamond Chain & Mfg. Co., Indianapolis, Ind. As assistant general manager he was in charge of the production during the war.

Upon leaving the Diamond Chain & Mfg. Co. he went to Baltimore, Md., and became director of the Red Cross Institute for the Blind, which was commissioned with the responsibility of giving vocational training to the blinded of the military forces. He left the Red

Cross Institute for the Blind on Jan. 1, 1921, to take charge of the investigation being conducted by the committee on elimination of waste in industry, appointed by Herbert Hoover.

He is author of a treatise on steel freight car design which is used by several universities as a text book; also prepared a number of instruction booklets for educational departments of railway companies; contributed various papers to railway and industrial engineering societies, papers covering varied topics pertaining to the activities of these two general groups.

Mr. Wallace is a member of the American Society of Mechanical Engineers and vice-chairman of the society's management section. He is now serving his third term as president of the Society of Industrial Engineers and is a past president of the Indiana Engineering Society. Mr. Wallace is a member of the International Railway

Fuel Association, Western Railway Club, Master Car Builders Association, Academy of Political and Social Science, and Western Efficiency Society. Mr. Wallace is prominent in Masonry, and is a past grand lecturer of the Grand Lodge of Indiana.

Mr. Wallace's social and commercial activities embrace a wide range. His work in New York as vice-chairman of the committee on elimination of waste in industry has been instrumental in bringing national attention to the purposes of the Council.

In an address before Engineering Council in Washington he summed up his idea of the function of the engineer as follows:

"It is the function and province of the engineer to make the correct analysis, to predict effect through known causes. It is purely the mission of the engineer of wide experience, of great foresight and of unselfish motive to see to it:

"First—That every action is based upon the principles of honesty, justice and fairness to the employee, the employer and the public.

"Second—To so formulate the plan of action as to eliminate all unfair privilege of employer and employee and to make it possible for each to fulfill its responsibilities to the community.

"Third—To so organize the plant or industry as to make it exceedingly difficult for an incompetent to hold a position of authority or to have autocratic control."

Mr. Wallace, now at the temporary headquarters of the Council in the Engineering Societies Building, New York City, will soon transfer his activities to Washington, where the Council has established permanent national headquarters in the McLachlen Building. The Employment Service Bureau will be continued in New York, with Walter V. Brown in charge.

LAWRENCE WILKERSON WALLACE
Executive Secretary, American Engineering Council

Current Events

in the Chemical and Metallurgical Industries

American Engineering Council Begins War on Waste in Industry

American Engineering Council of the Federated American Engineering Societies held a two-day session in Syracuse, N. Y., Feb. 14 and 15. At this meeting President Herbert Hoover announced the appointment of a committee on elimination of waste in industry as follows:

J. Parke Channing, Dr. Ira N. Hollis, L. W. Wallace, H. K. V. Scheel, L. P. Alford, George D. Babcock, F. G. Coburn, Morris L. Cooke, Harrington Emerson, E. E. Hunt, C. E. Knoeppel, Robert Linton, Fred J. Miller, J. H. Williams and Robert B. Wolf.

It was announced that the committee has already begun work and will study the nation as a single industrial organism to locate the weaknesses in the country's industrial system. An announcement by the Council says:

"The Federated American Engineering Societies, in which the national and local engineering societies of the nation are coalescing, is organized for public service. Unemployment, intermittent employment, strikes, lockouts and restrictions of output are waste. Disuse and misuse of machinery and equipments and losses of manufacturing materials are likewise waste. Stabilization of industry is a crying need, and also an engineering problem. Labor, capital, management and the consuming public stand to gain if common constructive action can be taken to lessen the idleness of men, idleness of productive equipment and the utilization of material."

The Council gave formal approval to the action of the committee on procedure requesting that President Harding put an engineer on the Interstate Commerce Commission. The procedure committee was authorized to name six qualified engineers when requested to do so. Activity in behalf of a National Department of Public Works will be continued by the Council through the public affairs committee. It was recommended that engineering efforts be extended to the whole question of Government reorganization planned under a special congressional committee.

The plan for the registration of engineers as presented in the Council's report was indorsed and the appointment of another committee was authorized.

An invitation from Philadelphia engineers to hold the April meeting in that city was accepted. The June meeting will be held in St. Louis.

The Council decided to recommend to President Harding that an engineer be appointed Assistant Secretary of War. No action was taken relative to the National Civic Federation, Fuel Conservation or Merchant Marine committee appointments.

Alloy Steel Patent Case Before Supreme Court

A case which may have a far-reaching affect on all chemical patents is now before the Supreme Court of the United States. The Churchward International Steel Co. has petitioned for a writ of certiorari in its case against the Bethlehem Steel Co. The Churchward company is the owner of certain patents covering alloy steel. It is alleged that the Bethlehem Steel Co. has infringed on these patents. The issue in the case, however, is the validity of the patents. The trial court found them to be valid and infringed. The Circuit Court of Appeals for the Third Circuit, however, reversed the lower court on the validity of the patents. The Circuit Court of Appeals' finding was based on an assumed inutility of the patent alloys and on an assumed lack of novelty in the alloy composition.

The Churchward company makes the point that if the patent alloys are of no special merit the Bethlehem company would be in the position of defrauding the Federal Government for selling such steel at a price of \$800 per ton. More-

over, it is pointed out that if the steel made by this formula had no special merit the safety of naval officers and sailors was menaced by the use of this steel in naval craft. The Churchward company also claims in its petition to the Supreme Court that if the decision of the Circuit Court of Appeals should be allowed to stand it would "result in the imposition of the burden of proof on inventors in the chemical arts, not imposed on any inventor in the mechanical arts, and a burden which has no statutory foundation, for Judge Woolley holds that to be patentable a chemical composition must be not only new, original and useful but must possess marked superiority. Such a doctrine is in conflict with the established precedence in the mechanical arts, where the similar test of patentability is one of utility and not of comparative utility."

The Churchward company states in its petition to the court that the Carnegie Steel Co. had infringed on these patents but that the matter had been settled out of court by payment of \$275,000.

Plan Symposium on Drying for Rochester Meeting, A.C.S.

The Division of Industrial and Engineering Chemistry will hold a symposium on drying at the Rochester meeting of the American Chemical Society during the week of April 25, giving particular attention to the six points of interest to the chemical engineer. These points have been selected as follows:

1. Transmission and distribution of heat in drying.
2. Temperature control of material in drying.
3. Effect of atmospheric conditions in drying.
4. Economy in drying.
5. Cost of drying.
6. Solvent recovery.

Thus far papers have been obtained from authorities on rotary driers, solvent recovery, compartment driers, vacuum drying and spray drying.

The chairman of the committee organizing this symposium is Charles O. Lavett, of the Buffalo Foundry & Machine Co., Buffalo, N. Y.

Industrial Survey Being Made at Old Hickory

As a part of its plan for industrial development at Old Hickory the Nashville Industrial Corporation is having a survey made of the whole powder plant. This investigation, which is being conducted by Meigs, Bassett & Slaughter, Inc., chemical engineers, of Philadelphia, will cover in detail possible uses for and means for disposing of the various units of the plant, which include:

Fifteen contact sulphuric acid plants, 7 nitric acid plants, 7 cotton purification plants, 7 cotton dry houses, 9 nitrating houses, 5 mix and weigh houses, 9 boiling tub houses, 9 pulping houses, 9 poacher houses, 16 solvent recovery houses, 1 diphenylamine plant, 1 causticizing plant, 4 box factories, 3 chemical laboratories, 3,500-ton refrigerating plant.

The diphenylamine plant is especially adaptable for a dye-making company, and is a separate and distinct unit in itself, having a 1,500-hp. steam plant, its own refrigerating system, independent warehouses, a hospital and a restaurant. It is located sufficiently distant from the village to protect the inhabitants from any fumes therefrom.

Some of the factors which are favorable to the establishment of manufacturing plants at Old Hickory may be summarized as follows: A power plant capable of supplying more steam and electricity than a community of 30,000 could use; a water reservoir and filtration plant which could meet the needs of a city the size of Boston; 1,138 six-room houses for which only a small rental is asked; excellent sanitary arrangements.

Duty on Potash Asked

A duty of 50c. a unit on imports of potash has been asked by the United States Potash Producers Association. Wilbur LaRoe, Jr., appeared for the domestic producers. He laid particular stress on a statement that the potash industry has a highly diversified ownership and that it is in no way controlled or influenced by the packing industry. Mr. LaRoe points out that the duty asked is only 20 per cent of the present price of potash. He stated that the industry was born under war conditions when potash was worth \$5 a unit. He said that the freight rate from the West to the East is 60c. a unit. In connection with his testimony, Mr. LaRoe submitted a number of tables, among which are the following:

POTASH PRODUCTION AND CAPITALIZATION, 1920

	Number of Producers	Production, Salts, Tons	Production, K ₂ O, Tons	Per Cent of Total	Capital Invested
Natural Brines:					
Nebraska lakes..	8	84,168	21,439	44.0	\$7,846,000

The American Fertilizer Industry

The present status and tendencies in the fertilizer industry were discussed from many points of view at a symposium of the Chemical Society of Washington on Feb. 10. At this meeting fertilizer use, phosphates, potash, nitrogen resources, fertilizer utilization and the future prospects of concentrated chemical fertilizers were all discussed by specialists in these fields.

TENDENCIES IN FERTILIZER INDUSTRY

William D. Hurd, director of the soil improvement committee of the National Fertilizer Association, summarized the present tendency of the industry. The relation of fertilizer use to the quality and quantity of crops produced was especially emphasized, and it was pointed out that this, the largest heavy chemical industry, is operating through 700 plants which produced in 1920 over 7,000,000 tons of product valued at over a quarter of a billion dollars. Some of the tendencies of the industry are particularly important. Those emphasized by Mr. Hurd were: A change from scavenger to chemical industry; the production of fewer brands; the use of higher percentages of plant foods in the fertilizers; the sale on the basis of pounds of plant food required per acre instead of pounds of fertilizer per acre; the use of domestic sources of raw materials previously imported; the adaptation of fertilizers to plant needs with particular attention to plant physiology; a clearer recognition of proper selling methods and an improved standard of ethics throughout the industry; the tendency to throw aside old long-held fallacies and emphasize the scientific business of farming.

PHOSPHATES AND PHOSPHORIC ACID

W. H. Waggaman of the Bureau of Soils discussed the present phosphate situation and certain suggestions for phosphoric acid production in relation to fertilizer development. He pointed out that America is independent of foreign sources of phosphate, a condition quite in contrast

to that found during the war period with respect to nitrogen and potash, the two other important fertilizer constituents. It is estimated by the Bureau of Soils that there is a reserve of phosphate materials of at least ten billion tons. These reserves are being drawn upon extensively in Florida, Tennessee and South Carolina and to a very much lesser degree elsewhere. These three states furnished approximately 2,500,000 tons, 500,000 tons and 50,000 tons respectively in 1920. The most serious aspect of the phosphate development is the large waste due to washing and screening of the product during preparation. It is estimated that only 15 per cent of the rock mined is saved and that more than twice as much phosphate goes on to the dump as to the market.

It was the effort to save these wastes of phosphate that led the Bureau of Soils several years ago to develop a pyrogenic method for phosphoric acid production which has been described (see *CHEMICAL & METALLURGICAL ENGINEERING*, p. 1057, Dec. 1, 1920). It is believed that the process described can be operated electrically to give phosphoric acid as cheaply as from the sulphuric acid method when power is available at \$25 per hp.-yr. When oil-firing is used the cost for fuel is only one-third. Hence under most circumstances it is believed that this will be a most economical system. The application of the phosphoric acid to phosphate rock produces the most concentrated phosphate fertilizer, perhaps best characterized as "treble" phosphate because it contains about three times the available P₂O₅ that is usual.

EFFECT OF BORAX

In a number of cases the problem of borax has been considered very serious. In fact during a single year the losses due to borax in the salt resulted in tremendous losses especially to Maine potato crops. A full discussion of this point at the meeting showed that it is no longer a problem to be feared, as salts well under one-half of 1 per cent borax are now supplied and in every case a guarantee not to exceed 1 per cent can be observed.

NITROGENOUS MATERIALS

Nitrogen resources and the possibilities and requirements of the country were discussed by Captain D. P. Gaillard of the Nitrate Division of the Ordnance Department. He pointed out the import situation, the relative importance of domestic nitrogen sources and the present status of nitrogen demand with prophecies for ten years to come. These phases of the subject have already been fully discussed in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 22, pp. 783 and 841.

CO-ORDINATION OF SOIL, PLANT AND FERTILIZER

Dr. Oswald Schreiner of the Bureau of Plant Industry pointed out in his discussion that fertilizer as applied to the soil is really a raw material of food production and agricultural manufacture. Viewed from this standpoint, it is necessary in fertilizer utilization to plan upon proper co-ordination of soil, plant and fertilizer. The work of the Bureau of Plant Industry on this subject was described by Dr. Schreiner particularly with reference to the proper selection of fertilizer types for different soil types.

POTASH SITUATION

The potash situation of today was discussed by F. W. Brown, secretary of the U. S. Potash Producers Association. Mr. Brown contrasted the present situation under which many potash producers of America have been compelled to suspend operations with the conditions which prevailed during the war period. He estimated that the production in 1920 amounted to 175,000 tons of potash salts, or 40,000 tons of K₂O. Of this the Nebraska lakes supplied 44 per cent, other brines 34 per cent. At the present time most of the small Nebraska plants are closed, but eight of the large companies are still operating. Whether they will continue successfully depends upon the measure of protection granted as a result of the present tariff legislation.

The 1920 potash operations demonstrated, according to Mr. Brown, one very important fact—namely, that these plants could operate on brines containing not over 3½ per cent of solids. The 1920 season was excessively rainy and

operation on these low percentage brines was therefore necessary, whereas previously a 7 per cent brine was considered the minimum which could be commercially worked. In Mr. Brown's opinion, this experience has demonstrated the almost indefinite extension possible in the potash brine development. The separation processes now are giving 45 per cent salt instead of 25 per cent salt formerly supplied and caustic and soda ash are becoming important sources of byproduct income.

CONCENTRATED FERTILIZERS

R. O. E. Davis of the Bureau of Soils discussed the subject "Concentrated Chemical Fertilizers, A Future Prospect." This discussion brought out the possibilities of using as fertilizers potassium and ammonium phosphates and potassium or ammonium nitrates. Two methods of application are available: First, by solution in water and sprinkling upon the land, and second, by mixing with soil on the farm to permit application by drilling into the soil as is now customary with mixer fertilizers.

The discussion of this subject brought out the possibility which is recognized by some that the use of chemical fertilizers may not answer the entire need of the plant any more than use of concentrated food without vitamins will answer the human need for food. However, it was pointed out that the soil as an active bacterial culture, which in effect it is, probably can care for these other needs without the artificial addition of these materials. The discussion also brought out the interrelation of many of the fertilizer problems with other industrial chemical problems of great importance, all of which emphasizes the importance to the chemical industry of this field of industrial activity.

Barrels and Cans for Petroleum Products

The manufacture of barrels and tin cans was explained and illustrated Monday evening, Feb. 7, before the Rochester Section of the American Chemical Society by Florus R. Baxter, chief chemist of the Vacuum Oil Co. Mr. Baxter told how years ago all barrels were made by hand and a man who could make ten or twelve barrels a day was a rapid worker. Now machinery has been invented and improved so that the greater part of the barrels are made by machinery. The present capacity of the Vacuum Oil Co.'s Rochester plant is about one million barrels a year.

To make these million barrels requires an enormous amount of materials—for instance, about eighteen million staves, one million pair of heads, and quantities of iron hoops, glue and paint. About four thousand acres of timber land is required for each year's supply. These timber lands are in Arkansas, Kansas, Kentucky, Tennessee, Alabama, Mississippi, Louisiana and Georgia.

First the lumber camp is established. The trees usually cut are those 50 ft. high and 2 ft. in diameter. No trees less than 14 in. in diameter 7 in. from the ground are cut. It takes about thirty years for the young trees to develop the required size. After the tree has been cut it is sawed into required length for staves or heads. The lengths for the staves are sawed on a cylinder so they are curved a little, and the staves are piled up in the air to dry. After the air-drying they are piled on edge and kiln-dried. The heads are cut out and piled in chimney form to air-dry for from three to six months. The staves and heads are shipped from the lumber camps to the factory.

The actual making of the barrel now begins. The staves are fitted inside a head hoop, and steamed to soften the staves so they may be bent. After bending the truss hoop is then put on and the moisture dried out. The bung hole is next put in. The iron hoops are next riveted together and flared on a machine and put on the barrel in place of the truss hoops. The ends of the staves are beveled and the groove cut to accommodate the heads.

The barrels are then inspected and all worm holes filled. The inside is covered with glue by putting glue inside the barrel and rolling it down an irregular incline so the glue is evenly distributed. Next the barrel is aged for ten or fifteen days, after which the hoops are again driven on. Another heavier coating of glue is put on the inside and allowed to dry. The barrel is then painted and dried, and

painted again and cured in a forced air drier. After inspection it is weighed and the weight stenciled on.

Now the barrels go to the filling room, where they are filled, automatic fillers being used. The bung holes are filled with a wooden plug and the oil is ready for shipment after being weighed and the gallons of oil computed. In the cars the filled barrels must be carefully wedged to keep them from rolling about.

TIN CANS

Mr. Baxter then took up the manufacture of the 1-gal. and 5-gal. tin cans. Most of the tin comes from Cornwall, England, although lesser amounts are found in other parts of the world. The tin is extracted from the ore by roasting. After several washings and smeltings the pure tin is recovered. Sheets of tin plate are formed, using a coating of palm oil, which is later removed by bran or sawdust. Then the sheets are decorated to suit the manufacturer. In this case they are enameled white and the trade mark is stenciled on.

The cans are made on machines which turn a hem on the sheet of tin and later close the seam. The tops and bottoms are put on and the seams soldered. The spout is then put on and after testing the cans go to the filling room. The cases in which the cans are packed are also made at the factory.

Throughout the factory and in the loading of cars, wherever possible, the barrels and cans are transported on conveyors.

Average Wages in New York Chemical Plants for November, 1920

A report issued recently by the New York State Industrial Commission gives the average weekly earnings in representative manufacturing industries in New York State for November, 1920. Figures for the corresponding month in 1914, 1916, 1918 and 1919 and the per cent increase of

AVERAGE WEEKLY EARNINGS IN NEW YORK STATE FACTORIES

1920 over 1914 are given for comparison. Employees in both office and shop are included, the effect of higher office salaries on the average being offset by the small number of office employees. Figures of interest to the chemical and metallurgical fields are given in the accompanying table.

New Tariff for Camphor Proposed

An attempt is being made to embody in the emergency tariff bill a duty of 50 per cent ad valorem on camphor. This step is taken in the interest of the synthetic camphor industry in the United States. The emergency tariff is being confined to agricultural products, but it is being argued that the income from turpentine recoveries forms an essential part of the revenue of farmers in the naval stores belt.

Among the articles added to the emergency tariff bill by the Senate is sugar. An additional duty of 1c. per lb. is provided.

Chicago Chemists' Club Smoker

The members of the Chicago Chemists' Club held an informal smoker at the quarters, 315 Plymouth Court, on Wednesday, Feb. 9. The address of the evening was delivered by Dr. Rollin B. Salisbury, dean of the Ogden Graduate School of Science, University of Chicago, who spoke on the origin of the earth. It seems that the earth is not a hot ball thrown off from the sun as is popularly supposed, but was developed by the accumulation of great numbers of smaller bodies revolving about the sun. The earth is still accumulating such material at the rate of about 50,000,000 meteorites per day. It is estimated that human life existed on the earth at least 1,500,000,000 years ago. He spoke of the work of English scientists in determining the age of rocks by use of radio-active substances. Without reference to religion the principal point of informal discussion centered around the origin of the original mass of matter or nucleus from which the solar system was developed.

The Drying of Paper

The regular February meeting of the Connecticut Valley Section of the Technical Association of the Pulp and Paper Industry was held in Holyoke Tuesday evening, Feb. 15, with an attendance of seventy-five members.

Mr. Farnsworth of the Farnsworth Engineering Co. of Conshohocken, Pa. spoke on "The Drying of Paper," with especial reference to the system developed by his company. He said that drying conditions had been the subject of investigation for years, for proper drying constitutes one of the fundamentals of paper manufacture. The introduction of any system to the industry as a whole is virtually impossible. In fact, he said that strictly speaking his own company had no real system, for each paper machine represented a different problem. The many grades of paper made and the many different types of machines in use rendered anything standard out of the question. It is possible to start out with one general outline of procedure and vary the details according to conditions.

The system which he has worked out depends for its efficiency on being entirely closed. By means of special valves it is possible to keep the condensate under pressure and return it to the boilers at a high temperature, thereby saving a large amount of heat. In such cases the volume of make-up water added to the system to replace losses is very small. The essential feature in the system consists in passing steam through a reducing valve set at any desired pressure and then to a number of drying rolls on the dry end. These driers are in parallel and the amount of steam entering each one is controlled by a throttle valve.

The exhaust steam from this set of driers is collected in a header, the condensed water trapped off and the balance of the steam passes directly into a set of driers at the wet end. The amount of condensate here is much greater than at the dry end and the number of driers in the set is adjusted so as to make the condensation cause sufficient reduction in pressure to pull the steam rapidly through the first series of driers and thereby prevent the accumulation of condensed water in the drying cylinders and at the same time to remove air from them.

Steam coming out of the driers at the wet end flows into a special apparatus where the make-up water is added as a spray, thereby condensing part of the steam and creating enough reduction in pressure to insure a rapid flow of steam through all the driers at the wet end.

All this condensed water is above the boiling point; its exact temperature depends on the conditions of operation of the paper machine and the pressure maintained. It is collected in special tanks and blown back to the boiler feed tank by high pressure steam let in at the top of the collecting tanks by an automatic valve arrangement which operates only when the tank is full.

For most paper machines the driers may be divided into two sets in series parallel arrangement, although more divisions may be necessary for certain types, especially of board machines.

The problem of proper drying, he said, consists in getting a gradual rise in temperature all the way along the driers

with the wet end at the lowest temperature. This must be done in such a way as to get the greatest economy in steam possible in order to meet modern industrial conditions.

Meeting of the New York Chapter of the American Society for Steel Treating

The New York Chapter of the American Society for Steel Treating held its meeting on Feb. 15, at the Machinery Club, New York City. Colonel A. E. White, the national president of the society, was the speaker of the evening. He outlined the present status of the society and said that during the short period of its existence the membership has grown to 2,959 and that since September, 1920, three new chapters have been instituted (Syracuse, N. Y., Charleston, W. Va., and Gary, Ind.) and that the next annual meeting would in all probability be held at Indianapolis, Ind. He then presented his paper on "Alloy Steel, Its Rise and Secrets."

Colonel White reviewed the great importance of iron in our present-day life and the history of the rapid growth of the steel industry in the United States. Electric steel, which was first manufactured here in 1908, reached a production of about 511,000 tons in 1918 and about 2,000,000 tons in 1920 and is steadily gaining in favor. The growing demands of the automobile industry and of armaments have influenced the development of the alloy steel industry. He then spoke on the theories proposed by Osmond and Edwards on the relations which exist between the elements and their influence in alloy steels. Osmond classified the main elements entering into alloy steels according to their

atomic volume $\left(\frac{\text{atomic weight}}{\text{specific gravity}} \right)$ and grouped them into two

classes according to whether the atomic volume is below or above 7.2 thus:

Class I		Class II	
Element	Atomic Volume	Element	Atomic Volume
C	3.6	Cr	7.7
B	4.1	W	9.6
Ni	6.7	Si	11.2
Mn	6.9	As	13.2
Cu	7.1	P	13.5
		S	13.7

Edwards uses the classification as given in Mendeleef's periodic table of elements. Colonel White also spoke of the laws of Léon Guillet on the influence of the variations of the carbon content, or of the special elements, or of both, on the constitution of the alloys. A series of equilibrium diagrams were shown to illustrate the theory of the coefficients of equivalence as applied to alloy steels. (Guillet's theory of the coefficient of equivalence as applied to ternary alloys was published in *CHEMICAL & METALLURGICAL ENGINEERING* of Jan. 26 and Feb. 9, 1921, pp. 177 and 261.)

In the discussion that followed it was brought out that zirconium steel does not present any special useful property at present known.

Alleged Gas Injuries Being Investigated

Manufacturing chemists are being asked by the Chemical Warfare Service for data in regard to the effects of gases on workers. It is believed that valuable information can be secured from chemical plants that have been manufacturing gases over a period of years.

More than 900,000 claims have been filed with the Government for compensation based on injuries received while in the military service. Of this number about 25 per cent are for alleged injuries due to gas. Studies that have been made by officials of the Chemical Warfare Service indicate that injuries from gas usually are as well defined as are wounds from projectiles. They do not take much stock in the claims that there are delayed effects arising from poison gas. They have not been able to trace a single case of tuberculosis which they are satisfied had its origin in gas. In the matter of compensation claims, however, the Government apparently must bear the burden of proof. In that connection General Fries expects to go minutely into the

records of industrial employees who have been handling gases.

The Chemical Warfare Service has undertaken to investigate some of the alleged after-effects of being gassed. In several of the cases it has been shown conclusively that the claimant was in error in his assumption that gas is responsible for his condition.

Paris-Havre Oil Pipe Line Delayed

Owing to the drop in the price of coal in France and the general business depression, work on the proposed oil-pipe line between Havre and Paris has been indefinitely suspended after nearly 20,000,000 f. has been expended on preliminary work. However, plans will be completed by the Stewart Construction Co. of New York with the hope of construction being resumed in ninety days.

The project, which is being financed by the Atlantic & Gulf Refining Co. through a French holding company, was designed to supply cheap fuel to industries in Paris.

Dye Industry Lags Pending Action on Dye Legislation

Hesitancy on the part of dye manufacturers to lay out a definite program of production for 1921 in the face of uncertain dye legislation is shown by their delay in placing contracts for sulphuric and nitric acids. This was brought out in an analysis of contract renewals made by several large acid manufacturers for the purpose of explaining an unexpected decrease in the amount of acid placed on contract.

Personal

Dr. GEORGE BORROWMAN, who for thirteen years was professor of industrial and engineering chemistry at the University of Nebraska, subsequently to which he did some research work with Dr. J. E. Teeple of New York, has recently entered independent practice in Chicago.

A. H. JONES has taken over the metallurgical laboratory and engineering business of Charles Butters & Co., Salt Lake City, Utah, under the name of the A. H. Jones Co.

WILLIAM B. LEACH, JR., has been discharged as Captain, C.W.S., in charge of the Experimental Division, and is now assistant manager at the Mathieson Alkali Works, Inc., Niagara Falls, N. Y.

Dr. JOHN A. MATHEWS has been elected president of the Crucible Steel Co. of America. Dr. Mathews has been identified with the company since 1902, and was vice-president for about a year.

Major J. E. MILLS, professor of chemistry at the University of South Carolina, has been chosen as an official consultant of the Chemical Warfare Service. Major Mills went to France with the first Chemical Warfare troops and was among the last officers of that service to leave that country.

Dr. R. B. MOORE, chief chemist of the Bureau of Mines, has delivered a number of lectures recently on helium, one of which he gave at the University of Illinois Section of the American Chemical Society on Feb. 16.

A. V. H. MORY, of the Procter & Gamble Co., Cincinnati, was in Chicago recently.

J. G. NEWTON, formerly with the Cerro de Pasco Copper Corporation, La Fundicion, Peru, is associated with the American Smelting & Refining Co., Maurer, N. J.

Dr. CHARLES WADSWORTH, 3d, who received the degree of Ph.D. in 1916 from Harvard University and who has recently been in charge of research and developments at the plant of Zinsser & Co., at Hastings-on-Hudson, N. Y., is now chemical engineer with the Grasselli Chemical Co. at East Chicago.

Book Reviews

TEXTBOOK OF CHEMISTRY FOR NURSES AND STUDENTS OF HOME ECONOMICS. By *Annie Louise Macleod*. New York: McGraw-Hill Book Co. 180 pages, illustrated. Price \$2.25.

In this textbook the author has presented the subject in a manner readily understood by a layman, giving in a practical way the chemical principles underlying nutrition, dietetics and cookery. Nurses of the present day customarily have at least a high school education, which gives them more than sufficient knowledge of chemistry to make the book readily understood and applied. The author has kept her work well within the scope indicated by the title, as a consequence of which it can be purchased by nurses and students of home economics with the assurance that it will meet their needs.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, Feb. 18, 1921.

A marked improvement has taken place in the demand for general chemicals during the past week. All signs point to better business in the very near future and prices are showing more stability in many directions. Resumption of operation is going on steadily among textile mills and tanneries as well as in other branches of the consuming trades. A gradual expansion is also noted in the call for export shipments and inquiries have reached the chemical market from various foreign countries on a fairly large scale. Resale stocks have been steadily decreasing, while the output among large producers has been sharply curtailed. Under this condition manufacturers seem to be in better control of the situation than at any time previously and it looks as though the time is ripe for the pendulum to swing back on price movement. Any large inquiries that have reached the market for spot material have been filled with difficulty, and in some instances it has been surprising to see how little actual stock is held by second hands. Liquidation in the past few months has been quite thorough and almost every item is in a position to respond to any permanent expansion in the extent of demand.

Among the large chemical items that merited interest was *soda ash*. Inquiries for this basic chemical reached the market from some of the leading foreign countries. The domestic inquiry was also more active and sales of 100-ton lots passed at 2c. per lb. in single bags f.o.b. N. Y. Japan has come into the market again and an inquiry was noted for a large tonnage over the year for ash and caustic soda. Interest on the part of Japan leads prominent factors to believe that the Orient might be one of the first sections to recover from the present industrial slump. *Bichromate of soda* attracted attention at prices ranging from 8½¢@8¾¢. lb. Spot material showed a firmer tendency during the week and there appeared to be relatively little stock offered among second-hand interests. Sales of late have been confined mostly to small lots and it is said to be doubtful if a round quantity could be purchased without advancing quotations. Resale lots of light *soda ash* were offered sparingly at prices ranging from \$2.10@2.20 per 100 lb. in single bags. Barrels were quoted firm at 2½¢. lb. with only an odd car available here and there. Producers' prices for contracts still remain unchanged at \$1.72½ per 100 lb., bases 48 per cent, f.o.b. works in single bags. Holders of resale *caustic soda* are asking \$3.90@\$4 per 100 lb. in most quarters. An odd car could probably be bought at \$3.85 or thereabout, but the general market shows a strong undertone with no apparent pressure of resale stock to record.

Trading continued along quiet lines and the condition was reflected in a slight irregularity of quotations. Small lot sales of solid caustic were reported as high as \$4.10 per 100 lb. Manufacturers' contract prices remained unchanged at \$3.60 per 100 lb., basis 60 per cent, f.o.b. works for prompt and future shipments.

Sellers of *aluminum sulphate*, iron free, are quoting the market at prices ranging from 3½@4c. per lb., depending upon the quantity of the inquiry. The movement of late has been along quiet lines. Moderate quantities of the commercial variety are offered at 2½@2¾c. per lb. Spot *formaldehyde* in the open market is offered at 17½c. per lb. and it is intimated that actual round lot business would shade this figure. The demand is fair, with competition rather keen to secure what business is passing. Dealers are quoting moderate quantities of *prussiate of soda* at 16½@16¾c. lb. on spot and in some directions 17c. is asked. Shipments from abroad that are due to arrive this month are offered at 15½c. lb. Domestic producers are holding contract prices firm at 18c. lb. Limited quantities of *yellow prussiate of potash* were offered at prices ranging from 29@32c. per lb. ex-store N. Y., depending on sellers. Supplies of this chemical are said to be low at the present time. Moderate quantities of imported *bleaching powder* were offered by dealers at 2½@2¾c. per lb. on spot. Some interests stated that only small quantities could be purchased at the inside figure and quoted the market as high as 3c. per lb. Small drums were quoted at 3½@3¾c. per lb. according to seller. A fair inquiry was in the market and the tendency was reported firm. Irregular quotations on *nitrite of soda* have been named throughout the entire week. Sellers have quoted as low as 6c. and as high as 9c. per lb. Demand has not shown very much activity and most of the business placed was said to be within the range of 6@6½c. per lb.

Trading in *alcohol* during the past week took on a little more activity both in domestic and foreign quarters. Prices are quoted by leading factors at unchanged levels, but in view of the strong competition it is quite possible to do business at lower figures. *Ethyl alcohol* ranges from \$5.25@ \$5.50 per gal. for domestic consumption, while for export 55@58c. per gal. is heard. *Denatured* ranges from 54@60c. per gal. Pure *methanol* is offered at \$1.50 per gal., although the regular market is quoted at \$1.60.

COAL-TAR PRODUCTS

The tone of the coal-tar products market has improved somewhat during the past week and reports from various quarters of the allied markets are very encouraging from the standpoint of a wider spread of operations and the handling of orders on a larger volume. There is still little talk along contract lines. In the crude products the tendency is steady and some of the items are moving freer. *Benzene* is firmly held in first hands at 30@36c. per gal. *Naphthalene* flakes, prime quality, holds at 9c. per lb. and in second hands at 8@8½c. Dealers' offerings of intermediates have been available in various quarters and sellers have shown little intention of naming any lower levels among their offerings. First hands are quite steady in their views with their prices listed somewhat higher, although firm orders on round lots might bring about shading.

Aniline oil seemed to be easy in some quarters while *para-nitraniline* is reported firm, with one manufacturer quoting \$1.05 per lb. on contract basis. Producers of *beta naphthol* are firm in their views on prices and quote on a basis of 42@45c. per lb. Offerings of cheap resale lots have been diminishing of late and the best quotation obtainable was 32c. per lb. The consuming element of *dimethylaniline* is still holding to a hand-to-mouth buying. Producers are firm in their views at 60@65c. per lb., while resale material ranges from 50@55c. Factors report the market for *meta-phenylenediamine* rather dull, with material available in fair volume and moving slowly in a routine manner on a basis of \$1.25@\$1.30 per lb. A fairly steady demand of a routine nature continues for *monochlorbenzene*. Producers report a regular output and quote prices steady at 14@16c.

per lb. Manufacturers of *para-phenylenediamine* seem to be in fair supply while the outside market has little to offer. Trading is picking up and prices are holding steady at \$1.90@\$2.20 per lb. A steady improvement in the fur industry will help bring about more stabilized prices for this commodity.

VEGETABLE OILS

The spot market for *chinawood oil* was irregular, with prices ranging from 9¼@10c. per lb. On the Pacific Coast prices were quotably unchanged at 8c. per lb. sellers' tanks and 8¼c. in cooperage. Trading in *coconut oil* was quiet, but prices showed very little change locally. *Ceylon oil* was held around 8½c. lb. sellers' tanks f.o.b. New York. There was a good call for spot *olive oil* and with supplies cleaned up the market at the close was more or less nominal. The uplift in exchange caused some operators to advance their prices for *palm oil* for shipment. *Lagos* closed at 7¾@7½c. per lb. c.i.f. New York. The market for crude *soya bean oil* was a dull affair among local dealers. Importers quote the market for shipment goods at 4¾@5c. per lb. sellers' tanks. For jobbing lots in barrels 7½@8c. per lb. seem to be the general quotations.

The Iron and Steel Market

PITTSBURGH, Feb. 18, 1921.

Last week's report noted that the steel market had suddenly begun to break. A week's experience with the "break" shows that it is a very tame affair indeed, altogether lacking in vitality. It is simply a case of the buying demand being so extremely light that it could not nurture a real break. This break is therefore altogether different from the various breaks in the steel market that have occurred in the past. The normal course in a break is for some mills to name cut prices and get some orders, whereupon other mills cut lower and get orders for themselves, other mills, or the first mills, then making fresh cuts, and so on. There must be some buying on the way down.

At the present writing many of the independent mills are naming cut prices from the Industrial Board or Steel Corporation prices, but a larger number are not, because they have not the opportunity. They are prepared to sell at reduced prices, but are awaiting bids by customers, or the expression of a willingness to buy.

Lowest prices actually done or quoted to date, as compared with the Steel Corporation prices, which represented the whole market after the independents reduced their prices to the corporation level late in 1920, are as follows: Bars, 2c., against 2.35c.; shapes, 2.25c., against 2.45c.; plates, 2.25c., against 2.65c.; plain wire, 3c., against 3.25c.; nails, \$3.10, against \$3.25; hoops, 2.85c., against 3.05c.; blue annealed sheets, 3.20c., against 3.55c.; black sheets, 4.15c., against 4.35c.; galvanized sheets, 5.35c., against 5.70c. Thus the declines range in general from \$4 to \$8 a ton.

In practically all the commodities mentioned there are mills willing to accept orders, if of reasonable size, at still lower prices. It is believed, for instance, that on a 5,000-ton order for plates 2c. could be done.

The trade generally attributes the starting of the break in the market to the Midvale Steel & Ordnance Co., which undoubtedly was the first interest to quote deep cuts to the trade at large. Inasmuch, however, as other independents within a few days decided also to make large concessions, even though they observed the Midvale company was not getting much business, the distinction is not an important one. It looks as though others would have taken the initiative within a short time if Midvale had not done so.

ATTITUDE OF INDEPENDENTS

The usual philosophy of steel makers, in a period of light demand, is that there is no use in reducing prices when buyers are not ready to take hold. Such a philosophy applied to the present situation would not countenance the price concessions that are so readily available. There is,

however, a difference, a situation that never before existed when the market was dull, the difference being that the Steel Corporation has been running at a high rate. From Dec. 1 to Jan. 15 the Steel Corporation produced at the rate of approximately 92 per cent of capacity, while the independents averaged a rate of scarcely more than 25 per cent, certainly not more than 30 per cent. In 1908 prices were maintained fairly well, but at that time the Steel Corporation's operations did not average as high as those of the independents. That was known at the time, and can be seen in the official statistics since compiled. Possibly the independents had no objection to the Steel Corporation running so well when they were almost idle, except for one circumstance, that consumers were getting the product. What the consumers were securing from the Steel Corporation they had no occasion to get from some other producer. Some independents felt that a redistribution, or a fresh start, was desirable from their viewpoint.

The Steel Corporation's operations were marked for a decline, but the break in independent steel prices is now causing the decline to be more rapid. The corporation operated at about 92 per cent of capacity in the fore part of January, and at somewhat under 90 per cent toward the close of the month. Its operations this week may be estimated at about 80 per cent, and the present outlook is that operations will decline at the rate of several per cent a week. Even at the beginning of the year some of the corporation customers were receiving more steel than they were currently consuming. With prices breaking, these buyers are unwilling to continue piling steel, and suspensions of shipment have become common. In some commodities the corporation's decrease in production in the next few weeks will not be fully equal to the decrease in shipping instructions, since the corporation can make stocks. This is quite feasible, as the corporation's production costs, while high, are not really excessive. The independents as a rule allowed their costs to mount so in 1920, when the money came in so easily, that it would be quite unbusinesslike now to make any stocks.

THE FUTURE

The first recasting of the steel market will require only a few weeks. Depending on the volume of buying, now too light to make a real market, the independents may develop something like a stable market. Then there is the Steel Corporation to be considered. It is not a question of whether the corporation will reduce its prices, but a question of when it will do so. The corporation may decide to reduce its prices when its operations get down to 60 per cent or 50 per cent or it may not reduce until it is operating at a lower rate than the independents.

As to demand, there will necessarily be an increase in the near future, for the present demand, in the open market, is almost nothing. The steel industry's capacity in finished rolled steel is in the neighborhood of 150,000 net tons per working day. The buying this week is not at a rate 10 per cent of that. The possibility of full operation again is such an indefinite one that it is not the subject of prediction or even conjecture. The nearby future presents a prospect of all mills striving to reduce their production costs, both for the purpose of being able to take orders without loss and for the purpose of broadening the demand for steel, which as a construction material must be at attractive prices. To illustrate, an estimate is made that of all the large skeleton steel or skyscraper office and hotel buildings in the country 85 per cent are built with steel contracted for when the steel market was at one of its low points.

PIG IRON

Since Jan. 1 the nominal market on bessemer iron has been \$32 valley, basic being nominally \$30. Of late it has been well known that steel interests, having surplus pig iron, would sell at much less, but actual quotations have been lacking. A large valley merchant interest has now voluntarily announced its asking prices at \$29 for bessemer and \$27.50 for basic, f.o.b. valley furnaces. There is no inquiry. Foundry iron remains nominally quotable at \$28 valley.

General Chemicals

Calcium chloride, fused, lump.....ton	27.00 - 29.00	30.00 - 32.00
Calcium chloride, granulated.....lb.	01½ - 02	02½ - 02½
Calcium hypochlorite (bleach'g powder).....lb.	02½ - 03	03½ - 03½
Calcium peroxide.....lb.		1.00 - 1.10
Calcium phosphate, monobasic.....lb.		15 - 16
Camphor.....lb.		75 - 80
Carbon bisulphide.....lb.	08 - 08½	09 - 09½
Carbon tetrachloride, drums.....lb.	11½ - 11½	12 - 12½
Carbonyl chloride (phosgene).....lb.		75 - 1.00
Caustic potash (see potassium hydroxide).....lb.		
Caustic soda (see sodium hydroxide).....lb.		
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	09 - 09½	10 - 10½
Chloroform.....lb.		38 - 40
Cobalt oxide.....lb.		3.00 - 3.10
Copper as (see iron sulphate).....lb.		
Copper carbonate, green precipitate.....lb.	22 - 22½	24 - 25
Copper cyanide.....lb.		50 - 60
Copper sulphate, crystals.....lb.	06 - 06½	06½ - 07
Cream of tartar (see potassium bitartrate).....lb.		
Epsom salt (see magnesium sulphate).....lb.		
Ethyl Acetate Com. 85%.....gal.		1.05 - 1.10
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.		
Formaldehyde, 40 per cent.....lb.	17½ - 17½	18 - 18½
Fusel oil, ref.....gal.		3.50 - 3.60
Fusel oil, crude.....gal.		2.75 - 3.00
Glauber's salt (see sodium sulphate).....lb.		20 - 21
Glycerine, C. P. drums extra.....lb.		3.85 - 4.00
Iodine, resublimed.....lb.		10 - 20
Iron oxide, red.....lb.		17.50 - 20.00
Iron sulphate (copperas).....100 lb.	1.25 - 1.50	
Lead acetate, normal.....lb.		14½ - 16
Lead arsenate (paste).....lb.	11 - 12	12½ - 13
Lead nitrate.....lb.		15 - 20
Litharge.....lb.	08½ - 09	09½ - 10
Lithium carbonate.....lb.		1.25 -
Magnesium carbonate, technical.....lb.	10½ - 11	11½ - 12
Magnesium sulphate, U. S. P.....100 lb.	2.00 - 2.50	
Magnesium sulphate, commercial.....100 lb.		1.50 - 1.75
Methanol, 95%.....gal.		1.28 - 1.30
Methanol, pure.....gal.		1.60 - 1.65
Nickel salt, double.....lb.		12 - 12½
Nickel salt, single.....lb.		13 - 13½
Phosgene (see carbonyl chloride).....lb.		
Phosphorus, red.....lb.	45 - 46	47 - 50
Phosphorus, yellow.....lb.		35 - 37
Potassium bichromate.....lb.	14 - 14½	14½ - 15

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar) . . . lb.	\$. . . \$. . .	\$0.30 - \$0.35
Potassium bromide, granular . . . lb.		.20 - .40
Potassium carbonate, U. S. P. . . . lb.	.35 - .40	.45 - .50
Potassium carbonate, crude . . . lb.	.08 - .08½	.09 - .10
Potassium chlorate, crystals . . . lb.	.08 - .10	.11 - .18
Potassium cyanide . . . lb.		.65 - .70
Potassium hydroxide (caustic potash) . . . lb.	.12 - .12½	.13 - .13½
Potassium muriate . . . ton	70.00 - 75.00	
Potassium iodide . . . lb.		3.00 - 3.20
Potassium nitrate . . . lb.	.09½ - .09½	.10 - .12½
Potassium permanganate . . . lb.	.48 - .50	.52 - .60
Potassium prussiate, red . . . lb.	.50 - .52	.53 - .55
Potassium prussiate, yellow . . . lb.	.28 - .29	.30 - .32
Potassium sulphate (powdered) . . . per unit		 2.25
Rochelle salts (see sodium potas tartrate)		
Sal ammoniac (see ammonium chloride)		
Sal soda (see sodium carbonate)		
Salt cake . . . ton		32.00 - 33.00
Silver cyanide . . . oz.		1.25 - . . .
Silver nitrate . . . oz.		.43½ - .44
Soda ash, light . . . 100 lb.	2.10 - 2.20	2.25 - 2.40
Soda ash, dense . . . 100 lb.	2.20 - 2.30	2.40 - 2.60
Sodium acetate . . . lb.	.05½ - .05½	.06 - .06½
Sodium bicarbonate . . . 100 lb.	2.50 - 2.75	3.00 - 3.25
Sodium bichromate . . . lb.	.08½ - .08½	.08½ - .09
Sodium bisulphate (nitre cake) . . . ton	7.00 - 7.50	8.00 - 11.00
Sodium bisulphite powdered, U.S.P. . . lb.	.05½ - .05½	.06 - .06½
Sodium borate (borax) . . . lb.	.08½ - .08½	.08½ - .09
Sodium carbonate (sal soda) . . . 100 lb.	2.00 - 2.25	2.50 - 2.75
Sodium chl. rate . . . lb.	.10 - .10½	.10½ - .11
Sodium cyanide, 96-98 per cent . . . lb.	.20 - .21	.22 - .28
Sodium fluoride . . . lb.	.13½ - .14	.14½ - .15
Sodium hydroxide (caustic soda) . . . 100 lb.	3.85 - 3.90	3.95 - 4.25
Sodium hyposulphite . . . lb.		.03½ - .04
Sodium nitrate . . . 100 lb.	2.85 - . . .	3.00 - . . .
Sodium nitrite . . . lb.	.06 - .06½	.06½ - .07
Sodium peroxide, powdered . . . lb.	.30 - .31	.32 - .34
Sodium phosphate, dibasic . . . lb.	.03½ - .04½	.04½ - .05
Sodium potassium tartrate (Rochelle salts) lb.		.29 - .31
Sodium prussiate, yellow . . . lb.	.16½ - .16½	.16½ - .17
Sodium silicate, solution (40 deg.) . . . lb.	1.10 - 1.15	1.20 - 1.40
Sodium silicate, solution (60 deg.) . . . lb.	.02½ - .03	.03½ - .03½
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.75 - 2.00	2.25 - 2.50
Sodium sulphide, crystal, 60-62 per cent (conc.) lb.	.05 - .05½	.05½ - .06
Sodium sulphite, crystals . . . lb.	.04 - .04½	.04½ - .05
Strontium nitrate, powdered . . . lb.	.17½ - .18	.18½ - .18½
Sulphur chl. ride, red . . . lb.	.07 - .07½	.07½ - .08
Sulphur, crude . . . ton	16.00 - 20.00	
Sulphur dioxide, liquid, cylinders . . . lb.	.08 - .08½	.08½ - .09
Sulphur (sublimed), flour . . . 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone) . . . 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent . . . lb.	.18 - .19	
Tin oxide . . . lb.		.45 - .47
Zinc carbonate, precipitate . . . lb.	.16 - .18	.19 - .20
Zinc chloride, gran . . . lb.	.11 - .11½	.11½ - .12
Zinc cyanide . . . lb.	.45 - .49	.50 - .60
Zinc dust . . . lb.	.12 - .13	.13½ - .14
Zinc oxide, XX . . . lb.	.08½ - .09	.09½ - .11
Zinc sulphate . . . lb.	.03½ - .03½	.04 - .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude . . . lb.	\$1.10 - \$1.15
Alpha-naphthol, refined . . . lb.	1.45 - 1.50
Alpha-naphthylamine . . . lb.	.38 - .40
Aniline oil, drums extra . . . lb.	.21 - .27
Aniline salts . . . lb.	.27 - .30
Anthracene, 80% in drums (100 lb.) . . lb.	.75 - 1.00
Benzaldehyde U.S.P. . . lb.	1.00 - 1.50
Benzidine, base . . . lb.	.95 - 1.05
Benzidine sulphate . . . lb.	.80 - .90
Benzoic acid, U.S.P. . . lb.	.70 - .75
Benzoate of soda, U.S.P. . . lb.	.70 - .80
Benzene, pure, water-white, in drums (100 gal.) gal.	.30 - .35
Benzene, 90%, in drums (100 gal.) . . gal.	.28 - .32
Benzyl chloride, 95-97%, refined . . . lb.	.30 - .35
Benzyl chloride, tech . . . lb.	.25 - .30
Beta-naphthol benzoate . . . lb.	3.50 - 4.00
Beta-naphthol, sublimed . . . lb.	.70 - .75
Beta-naphthol, tech . . . lb.	.32 - .35
Beta-naphthylamine, sublimed . . . lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.) . . lb.	.16 - .18
Ortho-cresol, in drums (100 lb.) . . lb.	.23 - .25
Cresylic acid, 97-99%, straw color, in drums . . gal.	.95 - 1.00
Cresylic acid, 95-97%, dark, in drums . . gal.	.90 - .95
Cresylic acid, 50%, first quality, drums . . gal.	.60 - .65
Dichlorobenzene . . . lb.	.06 - .09
Diethylaniline . . . lb.	1.20 - 1.30
Dimethylaniline . . . lb.	.55 - .65
Dinitrobenzene . . . lb.	.30 - .32
Dinitrochlorobenzene . . . lb.	.25 - .30
Dinitronaphthalene . . . lb.	.33 - .35
Dinitrophenol . . . lb.	.40 - .45
Dinitrotoluene . . . lb.	.25 - .30
Dip oil, 25%, tar acids, car lots, in drums . . gal.	.37½ - .40
Diphenylamine . . . lb.	.60 - .70
H-acid . . . lb.	1.30 - 1.50
Meta-phenylenediamine . . . lb.	1.25 - 1.30
Monochlorobenzene . . . lb.	.14 - .16
Monoethylaniline . . . lb.	1.75 - 2.00
Naphthalene crushed, in bbls. (250 lb.) . . lb.	.07 - .08
Naphthalene, flake . . . lb.	.08 - .08½
Naphthalene, balls . . . lb.	.08 - .08½
Naphthionic acid, crude . . . lb.	.70 - .75
Nitrobenzene . . . lb.	.12 - .15
Nitro-naphthalene . . . lb.	.30 - .35
Nitro-toluene . . . lb.	.18 - .25
Ortho-amidophenol . . . lb.	3.20 - 3.75
Ortho-dichlor-benzene . . . lb.	.15 - .20
Ortho-nitro-phenol . . . lb.	.75 - .80
Ortho-nitro-toluene . . . lb.	.20 - .24
Ortho-toluidine . . . lb.	.25 - .30
Para-amidophenol, base . . . lb.	1.90 - 2.00
Para-amidophenol, HCl . . . lb.	2.10 - 2.20

Para-dichlorobenzene . . . lb.	.15 - .25
Paranitroaniline . . . lb.	.90 - .95
Para-nitrotoluene . . . lb.	.90 - 1.05
Para-phenylenediamine . . . lb.	1.90 - 2.00
Para-toluidine . . . lb.	1.30 - 1.60
Phthalic anhydride . . . lb.	.55 - .60
Phenol, U. S. P., drums (dest.), (240 lb.) . . lb.	.10 - .12
Pyridine . . . gal.	2.00 - 3.50
Resorcinol, technical . . . lb.	1.85 - 2.00
Resorcinol, pure . . . lb.	2.30 - 2.50
Salicylic acid, tech., in bbls. (110 lb.) . . lb.	.23 - .25
Salicylic acid, U. S. P. . . lb.	.27 - .30
Salol . . . lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal. . . gal.	.28 - .32
Solvent naphtha, crude, heavy, in drums, 100 gal. . gal.	.16 - .18
Sulphanilic acid, crude . . . lb.	.30 - .35
Tolidine . . . lb.	1.35 - 1.45
Toluidine, mixed . . . lb.	.40 - .45
Toluene, in tank cars . . . gal.	.28 - .32
Toluene, in drums . . . gal.	.30 - .35
Xylidines, drums, 100 gal. . . lb.	.40 - .45
Xylene, pure, in drums . . . gal.	.42 - .45
Xylene, pure, in tank cars . . . gal.	.45 - . . .
Xylene, commercial, in drums, 100 gal. . . gal.	.33 - .35
Xylene, commercial, in tank cars . . . gal.	.30 - . . .

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark . . . lb.	\$0.24 - \$0.26
Beeswax, refined, light . . . lb.	.27 - .28
Beeswax, white pure . . . lb.	.40 - .45
Carnauba, Flora . . . lb.	.71 - .72
Carnauba, No. 2, North Country . . . lb.	.30 - .32
Carnauba, No. 3, North Country . . . lb.	.18 - .19
Japan . . . lb.	.19 - .20
Montan, crude . . . lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p. . . lb.	.04½ - .04½
Paraffine waxes, crude, scale 124-126 m.p. . . lb.	.04 - .04½
Paraffine waxes, refined, 118-120 m.p. . . lb.	.04½ - .05½
Paraffine waxes, refined, 125 m.p. . . lb.	.05½ - . . .
Paraffine waxes, refined, 128-130 m.p. . . lb.	.06½ - . . .
Paraffine waxes, refined, 133-135 m.p. . . lb.	.07½ - .07½
Paraffine waxes, refined, 135-137 m.p. . . lb.	.09 - .09½
Stearic acid, single pressed . . . lb.	.12 - . . .
Stearic acid, double pressed . . . lb.	.12½ - . . .
Stearic acid, triple pressed . . . lb.	.13½ - . . .

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940 . . . gal.	\$1.70
Pine oil, pure, dest. dist. . . gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035 . . . gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla. . . gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990 . . gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960 . . . gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970 . . . gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990 . gal.	.37
Pinewood creosote, ref. . . gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B- , bbl. . . 280 lb.	\$7.25 - . . .
Rosin E-I . . . 280 lb.	7.25 - . . .
Rosin K-N . . . 280 lb.	7.25 - . . .
Rosin W. G.-W. W . . 280 lb.	7.50 - . . .
Wood rosin, bbl. . . 280 lb.	7.75 - . . .
Spirits of turpentine . . . gal.	.58 - . . .
Wood turpentine steam dist . . . gal.	.56 - . . .
Wood turpentine, dest. dist. . . gal.	.55 - . . .
Pine tar pitch, bbl. . . 200 lb.	. . . - 8.50
Tar, kiln burned, bbl. (500 lb.) . . . bbl.	. . . - 15.00
Retort tar, bbl. . . 500 lb.	15.00 - 15.50
Rosin oil, first run . . . gal.	.50 - . . .
Rosin oil, second run . . . gal.	.52 - . . .
Rosin oil, third run . . . gal.	.60 - . . .

Solvents

73-76 deg., steel bbls. (85 lb.) . . . gal.	\$0.41
70-72 deg., steel bbls. (85 lb.) . . . gal.	.39
68-70 deg., steel bbls. (85 lb.) . . . gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.) . . gal.	.30

Crude Rubber

Para-Upriver fine . . . lb.	\$0.17 - \$0.18
Upriver coarse . . . lb.	.13 - .14
Upriver caucho ball . . . lb.	.14 - .14½
Plantation—First latex crepe . . . lb.	.19½ - . . .
Ribbed smoked sheets . . . lb.	.18½ - . . .
Brown crepe, thin, clean . . . lb.	.18 - . . .
Amber crepe No. 1 . . . lb.	.20 - . . .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls. . . lb.	\$0.09½ - \$0.09½
Castor oil, AA, in bbls. . . lb.	.10½ - .11
China wood oil, in bbls. (f.o.b. Pac. coast) . . lb.	.08 - .08½
Cocoonut oil, Ceylon grade, in bbls. . . lb.	.11½ - .12
Cocoonut oil, Cochinchina grade, in bbls. . . lb.	.12 - .12½
Corn oil, crude, in bbls. . . lb.	.08½ - .09
Cottonseed oil, crude (f. o. b. mill) . . . lb.	.05½ - .06
Cottonseed oil, summer yellow . . . lb.	.08½ - .08½
Cottonseed oil, winter yellow . . . lb.	.09 - .09½
Linseed oil, raw, car lots (domestic) . . . gal.	.70 - .71
Linseed oil, raw, tank cars (domestic) . . . gal.	.63 - . . .
Linseed oil, boiled, car lots (domestic) . . gal.	.72 - .73

Olive oil, commercial.....	gal	\$2 40	\$2 60
Palm, Lagos.....	lb.	.07	.07 ¹ / ₂
Palm, Niger.....	lb.	.06 ¹ / ₂	.06 ¹ / ₄
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.06 ¹ / ₂	.07
Peanut oil, refined, in bbls.....	lb.	.12 ¹ / ₂	.13
Rapeseed oil, refined in bbls.....	gal.	1.05	1.10
Rapeseed oil, blown, in bbls.....	gal.	1.15	1.20
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07 ¹ / ₂	.08
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04 ¹ / ₄	

FISH

Light pressed menhaden.....	gal.	\$0 46	\$0 48
Yellow bleached menhaden.....	gal.	.48	.50
White bleached menhaden.....	gal.	.50	.52
Blown menhaden.....	gal.	.85	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	
Blanc fixe, dry.....	lb.	.05	.05 ¹ / ₂

Chalk, English, extra light.....	lb.	.05	.07
Chalk, English, light.....	lb.	.05	.06
Chalk, English, dense.....	lb.	.04 ¹ / ₂	.05
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	40.00
China clay (kaolin), imported, lump.....	net ton	23.00	25.00
China clay (kaolin), imported, powdered.....	net ton	30.00	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	17.00
Fullers earth, granular, f.o.b. Fla.....	net ton	25.00	
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	
Fullers earth, imported, powdered.....	net ton	35.00	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.....	lb.		.09
Graphite, crucible, 85% carbon, Ashland, Ala.....	lb.	.07	.09
Graphite, higher lubricating grades.....	lb.	.11	.40
Pumice stone, imported, lump.....	lb.	.04	.50
Pumice stone, domestic lump.....	lb.	.05	.05 ¹ / ₂
Pumice stone, ground.....	lb.	.06	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		10.00
Quartz (acid tower) 1 ¹ / ₂ @ 2 in., f.o.b. Baltimore.....	net ton		14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	7.50
Shellac, orange fine.....	lb.	.65	
Shellac, orange superfine.....	lb.	.70	
Shellac, A. C. garnet.....	lb.	.57	
Shellac, T. N.....	lb.	.55	
Soapstone.....	ton	12.00	15.00
Sodium chloride.....	long ton		17.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	15.00
Talc, imported.....	ton	40.00	50.00
Talc, California talcum powder grade.....	ton	20.00	45.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	160
Chrome brick, f.o.b. Eastern shipping points.....	net ton	80-100
Chrome cement, 40-45% Cr ₂ O ₃	net ton	45-50
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	-55
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	55-60

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

FORDYCE—The Magnolia Petroleum Co. has awarded a contract to Schneider & Camp, Pine Bluff, Ark., for the rebuilding of the portion of its plant, recently damaged by fire with loss reported in excess of \$75,000.

California

PITTSBURG—The Pioneer Rubber Co., San Francisco, has awarded a contract to the Cahill & Vensano Co., 110 Sutter Street, San Francisco, for the erection of a new 1-story, reinforced-concrete plant at Pittsburg, to cost about \$50,500. Construction will be placed under way at once.

Connecticut

NEW HAVEN—The Seamless Rubber Co., Hallock Ave., manufacturer of rubber goods, has filed plans for the erection of an addition to its plant, including improvements to present works to cost about \$400,000, including machinery.

Florida

FERNANDINA—The Seminole Fertilizer & Oil Co. has tentative plans under way for the rebuilding of the portion of its plant recently destroyed by fire.

JACKSONVILLE—The Florida Paint & Cement Co., recently organized, has leased a local building for the establishment of a factory for the manufacture of technical paints. Local offices have been arranged at 302 Hill Bldg. H. A. Wheeler is president.

Georgia

SAVANNAH—The Southern Cotton Oil Co., 120 Broadway, has commenced the erection of its proposed new plant at Savannah for the manufacture of paint products. The factory with machinery is estimated to cost in excess of \$300,000.

Illinois

ALTON—The Consolidated Chemical Products Co. is planning for the erection of an addition to its local plant to be used for the production of muriatic acid and kindred specialties.

Iowa

HAMPTON—The Hampton Brick & Tile Co. is having plans prepared for the erection of a new brick and tile manufacturing plant with main building, 1-story, 40x200 ft., and a number of smaller structures, estimated to cost about \$250,000, including machinery. Claude Smith, Sheffield, Ia., is architect. J. C. Powers is secretary.

Louisiana

LAKE CHARLES—The Builders' Products Co. has plans under way for the erection of a new plant for the manufacture of hollow tile, paving brick and other burned clay products. Samuel Cummings is president.

Maryland

BALTIMORE—The Davison Chemical Co., Garrett Bldg., has arranged for a bond issue of \$2,000,000, the proceeds to be used for financing, operation and expansion. The company specializes in the manufacture of sulphuric acid, acid phosphate and other heavy chemicals. C. Wilbur Miller is president.

BALTIMORE—The Rasin - Monumental Co., National Marine Bank Bldg., a subsidiary of the Virginia-Carolina Chemical Co., Richmond, Va., specializing in the manufacture of fertilizers, has completed plans for the erection of its proposed new plant on the Patapsco River, and will take bids at an early date. The plant will be equipped for an annual production of 125,000 tons, and is estimated to cost about \$1,000,000, including machinery.

BALTIMORE—The Central Chemical Co., Pennington Ave., manufacturer of fertil-

izer products, has preliminary plans under way for the construction of a new building at its works. The company recently increased its capital from \$600,000 to \$1,000,000. M. H. Landers is head.

Massachusetts

MARBLEHEAD—The United States Upper Leather Co. has awarded a contract to the E. H. Porter Co., 15 Wallis St., Peabody, Mass., for the erection of a new 1-story building, 50x150 ft., at 278 B'way, Wyoma, to be equipped as a leather buffing department. Ernest Day is general manager.

RANDOLPH—The Randolph Foundry Co. has commenced the construction of a new 1-story foundry on Pleasant St., 50x75 ft., to cost about \$15,000. John Ferris is head.

Mississippi

NITTA YUMA—The Anguilla Cotton Oil Co. is planning for the rebuilding of the section of its plant destroyed by fire on Feb. 1, with loss estimated at about \$150,000.

Missouri

GERALD—The General Chemical Co., 25 Broad St., New York, is planning to open up a new mine at its local clay properties early in the spring, making the fourth such mine in operation by the company here. Equipment will be installed.

JEFFERSON CITY—John C. Dyott and associates are forming a company to construct and operate a local cement mill. Details of the new plant are being arranged.

Montana

MILES CITY—G. S. Bowser and B. C. Duggan are organizing a company to construct and operate a brick manufacturing plant on the Tongue River, near Fort Keogh, Mont. The plant will have an initial capacity of about 20,000 bricks daily.

New York

MASPETH—The United States Industrial Alcohol Co., 27 William St., New York, has awarded a contract to the George A. Fuller Industrial Eng. Co., 949 B'way, for the erection of its proposed new plant at Maspeth, on site at Grand St. and Harrison Ave. The works will comprise two brick and stone buildings, estimated to cost about \$500,000 with machinery.

NEW YORK—The Tide Water Oil Co., 11 B'way, operating an oil refinery at Bayonne, N. J., has arranged for a bond issue of \$12,000,000, the proceeds to be used for general financing operations and extensions. R. D. Benson is president.

BROOKLYN—The Botts Marking Ink Co., 330 Pearl St., New York, has leased the factory at 68-76 Third St., Brooklyn, for the establishment of a new plant.

BROOKLYN—Constant A. Benoit, Jerome Ave., manufacturer of chemicals, has filed plans for the erection of a new 3-story plant, 151x161 ft., on Ave. Y, near E. 17th St., to cost about \$225,000 with machinery.

North Carolina

GLENDON—The Tale Products Co. is planning for the erection of a new grinding plant with initial capacity of about 50 tons per day.

WITAKERS—The Woodard & Whitley Oil Co. is planning for the rebuilding of the portion of its plant, destroyed by fire on Jan. 22, with loss reported in excess of \$35,000.

WILMINGTON—The Fisheries Products Co. has preliminary plans under way for the construction of a new fertilizer plant on the Cape Fear River. A site has been selected. It is proposed to develop a capacity of about 40 cars of material per day.

Oregon

PORTLAND—The Portland Vegetable Oil Mills Co. has awarded a contract to the Hurley-Mason Co. for the erection of its proposed new plant on the site of the former shipyard of the Foundation Co., estimated to cost \$450,000.

New Jersey

TRENTON—The Trenton Zinc & Chemical Co., Broad St. Bank Bldg., manufacturer of zinc oxide, with plant at Fall and Fair Sts., has arranged for a stock issue of \$650,000. A portion of the proceeds will be used for plant expansion and it is proposed to increase the output from 2,000,000 lb. per year to 12,000,000. Considerable machinery will be installed for this purpose. Max Movshovitz, formerly president of the M. M. & S. Metal Co., manufacturer of similar products, is president of the Trenton Zinc & Chemical Co.

NEWARK—The Martin Chemical Co., 204-206 New Jersey Railroad Ave., heretofore occupying a portion of the building at this location, has purchased the entire property for increased operations. Alterations and improvements will be made, and additional equipment installed.

METUCHEN—The General Ceramics Co., 50 Church St., New York, will call for bids early in April for the erection of the proposed addition to its local plant, to be used for the manufacture of sanitary porcelain ware. The extension will be 1- and 2-story, 165x785 ft., and is estimated to cost about \$400,000, including equipment. Dietrich Wortmann, 116 Lexington Ave., New York, is architect.

TRENTON—The Bergougan Tire Co., Whitehead Rd., has resumed production at its automobile tire manufacturing plant, and plans to place a new addition in service at an early date. The structure is nearing completion, including machinery installation, and will provide considerable increased production.

Pennsylvania

PITTSBURGH—The Standard Sanitary Mfg. Co., manufacturer of sanitary ware, has acquired property in the Northside district, in the vicinity of its plant, near Ontario St. The site totals about 80,000 sq. ft., and was secured for a consideration of about \$135,000. It will be used for the erection of an addition, and existing structures on the land will be razed at an early date. The company is reported to be planning for the establishment of a branch at Baltimore, Md., and negotiations are under way for the acquisition of an existing factory here. The capital was recently increased from \$12,000,000 to \$20,000,000 for expansion.

READING—The Atlas Mineral Products Co., recently organized with a capital of \$100,000, is planning for the operation of mining properties in the vicinity of Mertz-town for the production of mineral paints, colors, compounds, etc.

Texas

PORT ARTHUR—The Gulf Oil Co., operating a large local refinery, has arranged for a bond issue of \$35,000,000 for general operation, financing and extensions. The company's present plant is now averaging 22,000,000 bbl. of crude oil per year. W. L. Mellon, Mellon Natl. Bank, Pittsburgh, Pa., is president.

CORSICANA—The Corsicana Oil & Refining Co. has perfected plans for the immediate construction of its proposed new oil refinery, comprising the first unit, estimated to cost about \$200,000, with machinery.

FORT BEND—The Fort Bend Cotton Oil Co. has disposed of its local plant to the state, and in the future it will be operated by convict labor. The Prison Department is reported to be arranging plans for extensions to give employment to an increased number of men.

DALLAS—The Gulf Refining Co., 315 Sherman St., has awarded a contract to the Bowden Construction Co., C St., Galveston, Tex., for the erection of an addition to its local refining plant to cost about \$160,000.

DALLAS—The Trinity Paper Mills is completing the erection of a new plant at Commerce, Tex., and plans to install machinery and place the mill in service at an early date. It will have an initial capacity of about 20 tons of pulp per day.

DALLAS—The Magnolia Petroleum Co. has preliminary plans under way for the construction of a new oil refinery at Port Neches, Tex. The company has a 500-acre site here for the proposed plant, which is estimated to cost in excess of \$300,000.

West Virginia

HUNTINGTON—The West Virginia Glass Mfg. Co. is planning for extensive additions in its plant for large increased capacity. Six additional blowing machines and considerable other machinery will be

installed. It is planned to triple, approximately, the initial output of the works. This is a new industry in the city.

LUMBERPORT—The Mound City Glass Co. is planning for extensions in its plant with the installation of considerable new machinery. It is planned to double the present output.

New Companies

THE D-K CHEMICAL Co., Nutley, N. J., has been incorporated with a capital of \$100,000 to manufacture chemical products. The incorporators are Ernest Keller, Howard M. Gensel and Gustave Kay-sch, Nutley.

THE CONSOLIDATED PAPER & TWINE Co., New York, has been incorporated with a capital of \$100,000 to manufacture paper and cordage products. The incorporators are D. B. Tolins, J. G. Cohen and B. Waxenberg, 291 Broadway.

THE ATLANTIC LEATHER CORP., Boston, Mass., has been incorporated with a capital of \$200,000 to manufacture leather products. The incorporators are F. H. Nesmith, H. P. Mason and J. Sidney Stone, 84 State Street.

THE S. G. PARKER Co., Brookline, Mass., has been incorporated with a capital of \$62,500 to manufacture chemicals and by-products. The incorporators are Patrick J. and Donald D. Flynn, and O. A. Atkins, Brookline.

THE COTTON STATES RUBBER Co., Atlanta, Ga., has been incorporated with a capital of \$500,000 to manufacture rubber goods. The incorporators are R. W. Ragin, G. J. Reuter and J. B. Anchors, Atlanta.

THE CENTRAL STATES PAINT & VARNISH Co., 38 South Dearborn St., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture paints, varnish, oils, etc. The incorporators are Charles Kramer, H. Kloth and Herman H. Sorem.

THE BURTOID Co., Paterson, N. J., has been incorporated with a capital of \$100,000 to manufacture chemicals and affiliated products. The incorporators are A. Lam-wers, Benjamin J. and Meyer W. Stein, 126 Market Street.

THE SYNTHOID Co., Inc., Boston, Mass., has been incorporated with a capital of \$50,000 to manufacture rubber products. The incorporators are Franklin W. Smith, Boston; Thomas L. Bronkhorst, Cambridge, Mass.; and Arthur V. Grimes, Brookline.

THE IBEX RUBBER CORP., Bound Brook, N. J., has been incorporated with a capital of \$125,000 to manufacture rubber goods. The incorporators are George O. Smalley, Bound Brook; William F. Jennings, Plainfield, N. J.; and Harry J. Lindsley, Detroit, Mich.

THE BEACON SMELTING & REFINING Co., Newark, N. J., has filed notice of organization to operate a plant at 3-5 Beacon St. Charles Friedman and Abraham M. Hein-owitz head the company.

THE CHASE OIL ASSN., INC., Boston, Mass., has been incorporated with a capital of \$100,000 to manufacture petroleum products. The incorporators are John M. Chase, George A. Fisher, and Joseph Schmanska, 51 Allston Street.

THE EDWARD E. ALLEN MFG. Co., Room 1016, 29 South La Salle St., Chicago, Ill., has been incorporated with a capital of \$50,000 to manufacture varnishes, enamels, paints, etc. The incorporators are Edward E. Allen and Louis A. Helle.

THE SOUTHERN INK MFG. Co., Houston, Tex., has been incorporated with a capital of \$25,000 to manufacture ink and chemical specialties. The incorporators are R. T. McDonald, J. C. Lemons and J. C. Kegans, Houston.

THE SYNTHETIC CHEMICAL CORPORATION, Landsdowne, Baltimore Co., Md., has been incorporated with a capital of 500 shares of stock without par value to manufacture chemical products. The incorporators are D. List Warner, John S. Short and Leslie E. Mahn.

THE H-W CHEMICAL Co., Columbia, S. C., has been incorporated with a capital of \$10,000 to manufacture chemicals and by-products. The incorporators are J. S. Hammack and J. W. Wilson.

THE JOLIET CARBONIC Co., 411 East Marion St., Joliet, Ill., has been incorporated with a capital of \$15,000 to manufacture acids, gases and byproducts. The incorporators are Walter F. and M. L. Pitcher, and Guy L. Meaker.

THE HALOGEN PRODUCTS Co., New Bedford, Mass., has been incorporated with a

capital of \$10,000 to manufacture chemicals, drugs, etc. The incorporators are George Mazel, Peter Cairns and Thomas N. Roche, 279 County St.

THE MAGNALOY METAL CORPORATION of America, 324 Bloomfield Ave., Montclair, N. J., has been incorporated with a capital of \$125,000 to manufacture metal alloys. The incorporators are Walter Lohry, Julius Kumpa and L. Friedmann.

THE PENN DISTRIBUTING Co., Camden, N. J., has been incorporated with a capital of 2,000 shares of stock of no par value to manufacture and deal in alcohol and kindred products. The incorporators are Joseph P. Murray, Frank S. Muzzey and F. Stanley Saurman. The Corporation Trust Co., 328 Market St., is representative for the company.

THE LA-LO CHEMICAL Co., Providence, R. I., has been incorporated with a capital of \$200,000 to manufacture chemicals and byproducts. The incorporators are E. J. Tetlow, C. E. Waterman and R. M. Green-law, Providence.

THE FRANKLIN DEVELOPMENT Co., Benton, Ill., has been incorporated with a capital of \$35,000 to operate an oil refining plant. The incorporators are James Austin, Hosea Rea and A. G. Sisk, Benton.

THE COLUMBIA PAINT Co., Columbia, S. C., has been incorporated with a capital of \$50,000 to manufacture paints, varnishes and affiliated products. The incorporators are W. J. Murray and A. S. Tompkins.

THE SOUTH KENTUCKY OIL & GAS Co., Burkesville, Ky., has been incorporated with a capital of \$50,000 to manufacture petroleum products and operate a refining plant. The incorporators are James A. McGartlin, Burkesville; H. A. Walton and Olaf A. Urseth, both of St. Louis, Mo.

THE UNITED SHALE BRICK Co., Ephrata, Pa., has been incorporated with a capital of \$100,000 to manufacture brick and other burned clay products. George W. Kinzer, Ephrata, is treasurer.

THE RAJET Co., Boston, Mass., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and byproducts. The incorporators are John K. Howard, Warren Matley and Dunbar F. Carpenter, 55 Congress St.

THE WILLIAM H. SCHUTTE Co., INC., 419-21 South Wells St., Chicago, Ill., has been incorporated with a nominal capital of \$5,000 to manufacture oils, waxes, industrial alcohol and kindred products. The incorporators are William H. and B. I. Schutte, and John J. Kelly.

THE NATIONAL CHEMICAL CORP., Stamford, Conn., has been incorporated with a capital of \$10,000 to manufacture chemicals and byproducts. The incorporators are P. J. Bowes, J. J. Roreck and A. S. Sorgi, 544 Main St.

THE REFRACTORY PRODUCTS Co., Fredricksburg, Va., has been incorporated with a capital of \$900,000 to manufacture refractory specialties and insulation products. The incorporators are W. S. Quigley, L. E. Turk and T. M. Calvin. The company is affiliated with the Quigley Furnace Specialties Co., 26 Cortlandt St., New York.

THE NATIONAL AGRICULTURAL CHEMICAL Co., Jersey City, N. J., has been incorporated with a capital of \$100,000 to manufacture fertilizer products, chemical derivatives, etc. The incorporators are Henry G. Feinberg, Benjamin Altman and P. C. Wilke. Charles H. Blohm, 286 Central Ave., is representative.

THE ST. JOHN'S CHEMICAL Co., New York, has been incorporated with a capital of \$50,000 to manufacture chemicals and byproducts. The incorporators are A. E. and E. H. Post, and C. J. Hyland, 457 Third Ave., Brooklyn, N. Y.

THE NORRIDGEWOCK LIMF Co., Norridge-wock, Me., has been incorporated with a capital of \$200,000 to manufacture lime, operate limestone properties, etc. The incorporators are Charles H. Hussey, F. R. Folsom and Eben S. Miller.

HAMMILL & GILLESPIE, INC., 240-42 Front St., New York, has been incorporated under Delaware laws with a capital of \$500,000 to operate clay properties, mine clay, etc. The incorporators are Hilliard M. Gillespie, William D. Hart and Frederick H. Stokes.

THE DISSOWAY CHEMICAL Co., Brooklyn, N. Y., has been incorporated with a capital of \$60,000 to manufacture chemicals and kindred products. The incorporators are E. J. Fenning, G. G. Dallan and T. N. Dissoway, 412 E. 7th St.

THE CHICAGO PORCELAIN Co., 1313 West Harrison St., Chicago, Ill., has been incor-

porated with a capital of \$10,000 to manufacture porcelain products. The incorporators are George T. Jennings, Gerald C. O'Brien and Leo N. Appgar.

THE RUMFORD PULP REDUCTION Co., Rumford, Me., has been incorporated with a capital of \$100,000 to manufacture pulp and paper products. The incorporators are Paul B. Hudson and George H. Murphy.

THE BUR-MAC CHEMICAL CORP., New York, has been incorporated with a capital of \$50,000 to manufacture chemical and byproducts. The incorporators are W. R. and W. C. Burrows, and M. E. McGovern, 1 Liberty St.

SAVELL & FROST, INC., Niagara Falls, N. Y., has been incorporated with a capital of \$150,000 to manufacture chemical products. The incorporators are A. Killian, J. G. G. Frost and W. L. Savell, Niagara Falls.

GEORGE E. MIGNON, INC., New York, has been incorporated with a capital of \$50,000 to manufacture chemicals and byproducts. The incorporators are George E. Mignon, J. R. Clarke and R. T. Tyner, 49 Liberty St.

THE CAZ CHEMICAL CORP., Atlanta, Ga., has been incorporated with a capital of \$100,000 to manufacture chemicals and by-products. The incorporators are E. Saperstein, Frederick Darbonnier and Leon M. Shimoff, Atlanta.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY, CHICAGO SECTION, plans to hold a joint meeting with the Illinois Clay Manufacturers Association of Chicago about March 8.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 and 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CANADIAN INSTITUTE OF MINING AND METALLURGY will hold its annual general meeting in the Chateau Laurier, Ottawa, Ont., on March 2, 3 and 4.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NATIONAL SAFETY COUNCIL, ENGINEERING SECTION, will hold its midwinter meeting in Philadelphia Feb. 28.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 342 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27, 28 and 29.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Sorts and Conditions of Men

WHEN we speak of all sorts and conditions of men we are likely to think more of their conditions than we do of their sorts—and we make a mistake in the lead. We can't gage the worth of a man by what he makes any more than we can gage the worth of an article by what it brings.

Let's cite an example on exposition of the latter statement. Imagine the affluent Mr. P. LUNJER walking into the establishment of a leading antiquarian on Fifth Avenue in New York. P. LUNJER is a patron of the arts, he is a collector, known as an amateur—in the true sense of the word—and his gallery is famous. He has lately returned from Italy and Spain, where he has been traveling and "picking things up."

The dealer in antiques has returned still more recently from abroad, where he has been over the same route. Two weeks after Mr. P. LUNJER visited Seville the dealer was also there, and he found in a second hand furniture store a picture that looked like a genuine Ribera. He bought it for ten dollars after finding out where it had come from. Then he spent a couple of days getting attests from notaries, and set sail for New York.

Mr. P. LUNJER is entering the Fifth Avenue door in response to a special invitation to be the first one to look at the dealer's great find. It is evidently designed to represent St. BONIFACE the Hospitable, and is a genuine Ribera without doubt. The curators of a number of museums recognize it as such and so does Mr. DAUBLESS, the eminent art critic. The dealer hates to let it go, but if Mr. LUNJER will permit him to exhibit it for six months he will let him have it for twenty thousand dollars. Mr. LUNJER does not want to wait so long: he wants it for his gallery immediately, and although it upsets the dealer's plans and he never meant to do it, he is finally persuaded to let Mr. P. LUNJER take it home with him in his automobile for twenty-five thousand dollars.

There we have a canvas that sold twice within three months, once for ten dollars, and once for twenty-five thousand. Whatever the value may be, the selling price does not indicate it.

It is very much the same way with men. We know individuals drawing ten, fifteen, twenty, and twenty-five thousand dollars a year that are not worth it at all outside their present jobs, and the only reason they get their pay is that somebody is an easy buyer; thinks himself a rare judge of men, mistakes boasts for performance, and—of such are our Feeble-Minded Heavy-Weights. On the other hand we know still more men who are pegging away at tasks that it would be flattery to call mechanical, and yet there are potentialities within them to do great things. They are ready, willing, and

anxious to serve with all their hearts, but the purchaser of their work does not see their value. He can't recognize their capacity. He has never even put them into a frame and looked at them.

Of course every one of us who would succeed must "hump himself" and look around occasionally. It is very well to preach the gospel of obedience, but obedience is merely an incident in the great art of getting along. Every man of affairs knows the misery of learning that he is to blame if things go wrong, from assistants who can't see the greater importance of keeping the whole establishment going right. If a lamp is upset and the house is afire it is more important to put out the fire than to learn who upset the lamp—and yet a great many persons can't understand this.

Every year there are hundreds of thousands of boys who leave school and go to work. The first desire of course is to work like a man and to get a man's pay. If he can feed a printing press or operate a passenger elevator he must first prove himself by being able to stick at it. Then comes the subtle gift to see that the work, no matter how well it pays, does not require intelligence; that it does not call for head work, and that if we spend our lives with our heads in idleness, our heads will not work when we want them to, either for us or for anybody else. So the mentally inert and those who lack the gift of faith in themselves stay along with those of feeble wit in the elevators or at feeding presses while the ambitious boys look for jobs where they can grow.

In the great ranks of labor these two sorts of men are bunched together by employers as well as by labor unions. This is a great mistake. The man with too much intelligence for a stupid job should not be kept at it. He may be able to leave it, but this is not always possible and the fault is just as likely due to the employer as to the employee, especially if work is scarce. One great reason why the man who outclasses his job should not be kept at it is because he is bound to become unhappy and discontented, and discontent is catching.

Let us take a well-known example of intelligence tests to illustrate our meaning. A pharmaceutical establishment employed young women to pack up boxes of pills. It was a steady job. They subjected applicants to intelligence tests, and graded them in classes from 1 to 10, one representing the lowest, ten the most intelligent. The efficiency of the workers was plotted on another curve, which rose quite rapidly up to grade 5, but fell off sharply and even declined for the high grades. Labor turnover also was chiefly in grades 7 to 10. The work was too dull for intelligent girls, and if they stayed on the job they lost heart and did not work well, while the best of them left as soon as they could afford to do so.

This rule holds among men as well as among women. We have intelligence and capacity with us in the shop

and in the office. If we do not recognize it, it will probably leave us. Then when we want talent we must go out and bid for it; bid high.

Now let us recall the journey of Mr. P. LUNJER through Seville bent on "picking up" art treasures and finding nothing, and the later journey of Mr. DEALER to the same place and his purchase of a dingy old canvas for ten dollars, and its subsequent resale for twenty-five thousand dollars. Having that in mind, let us recall that we are in the market for talent; that the progress of our business, whatever it may be, is largely a matter of talent.

Do we buy this talent like a man who knows it when he sees it? Or are we such easy marks that we can't see it until somebody else bids high for it or until we can see a sheet of past performances, often truly passed and not repeated?

Demonstrated Improvement—

The Best Argument for Protection

POTASH producers have appeared before the Ways and Means Committee urging a tariff of fifty cents a unit on imported salt, arguing that with this protection they will be enabled to continue the development of American potash to the point where it can meet fair foreign competition. Fortunately this industry has made a sufficient advance within recent years, or one might better say months, to make such a plea convincingly. Any infant industry which can demonstrate continuous improvement in plant processes and efficiencies can appear before Congress asking for temporary tariff protection with assurance of at least a respectful hearing from both parties.

Even its most vigorous advocates, however, do not claim that it has done all which it could have done in the way of technical improvement. Chemical control of brine plants and the application of sound physical and chemical principles have been conspicuously absent in many plants. Nevertheless certain parts of the industry have been advancing, demonstrating most effectively the value of pure science and applied scientific research.

In another way, too, this industry has, like many others, failed to do all that might have been asked of it. It is not essentially a competitive business, for the American demand far exceeds the domestic production, and will for years to come. All potash producers, therefore, will profit by active co-operation and exchange of technical information. However, instead of active co-operation, there has even been vigorous competition which has absorbed energies which might better have gone into development. This, fortunately, is rather aside from the main issue. The industry has advanced and on this basis deserves more careful consideration by our legislators than the many other mendicants now flocking to the feast.

Whether Congress will deem "national self-sufficiency" in potash important or not, one can but guess in the light of its performances toward other key industries. Since potash is a commodity made by few and used by many, and that many farmers, a cynical one might venture the prediction that a duty on potash will not be decided on its merits however great or small, but the question will particularly appeal to the free trade arguments tucked away in every legislator's equipment for use when it may increase the number of his votes.

Information on

Fatigue Failures

WÖHLER'S tests, published 50 years ago, confirmed the suspicion then held by constructors that beams or rods would fail under a relatively low stress if only repeated often enough. His research has since been the model for later investigators, who have sought to extend his conclusions regarding the relationship between range of stress and repetitions necessary for failure; evidently most important "practical" information. Most of the work was done with relatively heavy stresses, however, and did not disprove WÖHLER'S conclusion that each material possessed a "limiting stress" within which the number of repetitions necessary for rupture become infinite.

Infinity of course cannot be approached, but whereas the life of a bridge member, a rail, or even a car wheel might be compassed by the 20 millions of reversals attained by WÖHLER and his followers, the development of high-speed engines, turbines and electrical machinery raised anew the question of whether a recurring load, however small, might cause rupture, if only applied often enough. The Joint Investigation of Fatigue of Metals, under the able direction of Professor H. F. MOORE, has been able to show by means of dozens of tests that if the stress is not enough to cause failure in much less than 10 million alternations, it will not cause failure in 100 million. In other words, this investigation, still actively under way, has definitely confirmed the very important fact that each metal tested has a definite "endurance limit," a stress which may be applied to their test bars at least 100 million times without harm.

It is more than curiosity which impels metallurgists to inquire into the real mechanism of fatigue failure. An understanding of its nature is evidently precedent to accurate interpretation of present test data, correlation of other test results, development of short-time tests, and rational attempts toward provision of safer structures, either by more resistant materials or more skilled design.

At first it was thought that the fibrous tough elements comprising metallic articles were changed into growing crystalline particles, and these crystals then split open on their cleavage planes at the moment of fracture. However, microscopic examination has long since established the fact that metals and alloys are essentially crystalline aggregates, and there has never been any proof adduced that crystals increase in size under any circumstance of work or rest at atmospheric temperatures. Distortion under stress is known to be accompanied by crystalline disintegration rather than growth, and we even suspect that crystals are more ductile than that material which cements them together.

Secondly, BAUSCHINGER found that the elastic limit of mild steel, for instance, depended to a certain extent on its method of fabrication and heat treatment, and the figure ordinarily obtained was therefore dubbed the "primitive" elastic limit. When a specimen is subjected to stress reversals of growing amplitude, new or "natural" elastic limits in tension and compression appeared, within which the material would not fail by fatigue. This experimental conclusion suggests the hypothesis that some commanding portion of the material changes its elastic limit under alternating stresses.

However, recent studies into the ultimate structure of crystals have led to the proposal of the idea that fatigue failure is due to the spread of damage from

overstrained portions, microscopic in size. Stress concentrations at re-entrant angles and internal cavities have been shown mathematically to rise sometimes to six times the average. This fits in well with the latest hypothesis, which recognizes that metal is a complex and heterogeneous aggregate and accounts for the extreme sensitivity of the test to inclusions and surface finish, an experimental fact which finds striking support in the success one of our leading railroads has had in reducing axle failures by polishing the ends. In fact many things indicate that a fatigue break may be a property of a crystal rather than of a material; that is to say, ductile crystals are strong against fatigue, while unyielding amorphous metal has little resistance. Alternate stress therefore promotes rupture in all materials by changing ductile crystals into amorphous substance not so much by those internal earthquakes evidenced by slip planes as by tearing individual atoms from their regular locations. Under this supposition a high modulus of elasticity means a high endurance limit because the atomic motion for a given stress is correspondingly low and less liable to transgress the safe boundary; thus rubber or glass is poor, iron or steel good to resist alternating stress. For the same reason a stress between zero and $+40,000$ is much more dangerous than another ranging from $+20,000$ to $-20,000$.

No simple relationship between the fatigue endurance limit and any of the static properties has yet been discovered—in fact, Professor MOORE has found that ingot iron will withstand successfully 100 million repetitions of a stress equal to 160 per cent of its proportional limit, as determined from the usual tension test, yet a popular chromium-nickel analysis can be safely stressed no more than 60 per cent of its proportional limit. Other steels tested lie between these extremes, seemingly at random. Evidently further studies into the inner nature of fatigue, static and impact failure will be necessary before these tests can be correlated or a short-time fatigue test devised which will quickly indicate the reliability of new or doubtful material.

Most automobile users are sure that springs break under comparatively small shocks as compared to some of the bumps which left them whole; but is it really true that in general a few larger stresses greatly impair fatigue resistance? Does occasional annealing help or harm the resistance to repeated stress? Will a steel endure as long at a moderate temperature? Is there a relationship between endurance limit and amount of work absorbed by inelastic action? Does sudden application of load cause different results than the same total load applied in a harmonic manner? If so, what is the critical rate at which stresses may be built up? What is the result of loads which do not reverse from tension to compression, but simply range from a high pull to a low pull? What is the fatigue effect of alternate compression applied by direct longitudinal forces, in distinction to an equal stress at the outer fiber induced by flexure?

Machines have been devised for studying the last two problems, largely through a grant from the General Electric Company. Yet it may easily be recognized that the work now financed will only serve as a reconnaissance in the field of ferrous metals. It has been the experience of makers of springs, automobiles, and aeroplane-engines that ordinary static tensile results have comparatively little meaning to one anxious to pre-

dict performance of moving parts, lacking actual service tests. Since nearly all the high strength steels now being produced are subjected to recurring forces, the progressive concerns which absorb this expensive material simply cannot afford to allow this research to stop short of its goal. It is costing about \$15,000 a year. If it establishes data which will allow a saving of no more than one cent for every ton of alloy steel made in the United States, its annual cost is returned to industry.

Fluoresceine and Industrial Alcohol

SOME months ago when deaths from accidental poisoning by drinking methanol, or so-called wood alcohol, were a matter of almost daily occurrence we received an interesting communication from A. E. OUTERBRIDGE, Jr., a prominent metallurgist in Philadelphia, calling our attention to a simple method of deterring men from drinking denatured alcohol of known or unknown origin and thereby running the risk of methanol poisoning. Mr. OUTERBRIDGE explained that the addition of a small amount of fluoresceine to denatured alcohol, practically invisible in the concentrated solution, gave, on dilution with water to potable proof, a yellowish green fluorescence that would immediately attract the eye and cause the intending consumer to forego his drink. It was Mr. OUTERBRIDGE'S thought that if industrial alcohol could be thus treated men would think twice before drinking it, and that accidental poisoning from methanol would be greatly reduced. He brought this matter to the attention of the Prohibition Commissioner and subsequently sent us a small quantity of denatured alcohol to which had been added 7 milligrams of fluoresceine per 100 c.c. This we transmitted to the Prohibition Commissioner with the inquiry as to the possibility of obtaining his formal approval of the method and official adoption of the formula. His reply is printed elsewhere in this issue and we are glad to note that although he considers it inexpedient to require the addition of fluoresceine, because the coloring departed on dilution might be objectionable in some manufacturing processes, nevertheless he regards "the voluntary addition of fluoresceine to a factory stock of completely denatured alcohol or specially denatured alcohol . . . to be highly desirable."

If our readers desire to observe an interesting phenomenon let them repeat Mr. OUTERBRIDGE'S experiment and add a drop or two of alcoholic solution of fluoresceine to water. The fluorescent property of the chemical is magnified to an astounding degree and renders the alcohol repulsive in appearance for beverage purposes. We are assured by Mr. OUTERBRIDGE that in his personal experience this simple method of guarding against the consumption of industrial alcohol in the factory has been very effective, and we recommend its wider adoption.

Sir or Prince

IN a recent issue of *Chemical News* of London Mr. E. TOMLINSON writes from Barrow-in-Furness in regard to theories of the color of water propounded by Sir W. D. BANCROFT.

Sir WILDER sounds very well, but it hardly reaches. If titles were adjusted to personality and achievement one should be more disposed to regard him as Prince.

Readers' Views and Comments

Library and Research Work

To the Editor of Chemical & Metallurgical Engineering

SIR:—The New York Times of Sunday, Jan. 9, 1921, in its Editorial Section had a very interesting article on "Engineers Join in Research Work," with a sub-head "Agencies Co-operate in Effort to Salvage Knowledge Gained in War."

While the aim of this article is to make known the co-operation of the several large engineering societies of this country in linking together their members into a vast potential force for the solution of the various problems confronting the manufacturer and scientist, it has left out a very important link in this chain of research. I refer to the library link.

We all know that today, as never before scientists and manufacturers are depending more and more upon records of others as found in the printed word. Witness the growth of the service of the United Engineering Society, the generous response to the Chemists' Club for increased funds, the expansion of the technology room of the New York Public Library and, most important of all, the tremendous increase in special libraries organized since 1917 to aid large and small industries in the solutions of their problems. Now then, with the linking up of this vast reservoir of salvaged knowledge gained from the war together with knowledge that has been made available throughout past years, what greater ally to industrial research could be found?

To go back to March 25, 1915, the *Engineering Record* published an article the text of which was: "There are today in this country a large group of engineering libraries of great value collectively but not suitably co-ordinated." This article finishes by saying that: "To do the work would necessarily require considerable expenditure, but it would be time and money well spent."

It is not altogether unlikely that the following circumstance will be repeated many times, and to avoid it we should make a national effort to harness it. I refer to a happening in a large industrial city where a large manufacturing concern had been experimenting on a special process, resulting finally in failure. One of the men working on this process was talking with the librarian of the city about it. A smile crept over the librarian's face as he told the man that "that very experiment had been tried out before and found a failure. We have a record of that failure right here in one of our books." So because this concern went ahead blindly it lost thousands of dollars and was no further ahead.

So it goes and so it will continue to go—wasting thousands of dollars annually simply by failing first to find out whether or not the proposed process, operation or whatever it may be has ever been done before and if so what is the best way.

There are two ways that this "library link" can aid materially.

The first is by publishing weekly an index of abstracts of articles in current technical papers.

The second is the founding of a large central catalog

of all technical books, pamphlets, trade catalogs and translations, carefully analyzed for every item of value in them.

This proposed catalog would be a large undertaking but by no means unpracticable. A long start has been made in the Library of the United Engineering Societies, in the Library of Congress and John Crerar Library of Chicago. This proposed library has its prototype in the International Institute of Bibliography at Brussels, which fortunately escaped the ruthlessness of the Germans and recently filed its twelve-millionth card.

Additional co-operation could be gained by linking up the several hundred special libraries devoted to special industries by making them sponsors for picking out all items of pertinent value in their collections and sending copies of cards indexing these items to the proposed central catalog.

These two schemes for increasing research work of the future have been but briefly outlined. To some these two allies of research may seem remote and unpracticable. The fact that the International Institute of Bibliography has existed even through war-ridden days of Belgium long enough to file its twelve-millionth card is indicative of the commercial possibilities of a similar scheme in this country where the machinery for its accomplishment is greater.

Let us then make a determined stand to harness these forces and set them to work.

LIBRARIAN.

Advantages of Cadmium Lithopone

To the Editor of Chemical & Metallurgical Engineering

SIR:—Having been closely connected with the manufacture of lithopone and engaged in the designing of plants for the purpose for a number of years, the comprehensive article by H. R. Hanley on the production of electrolytic cadmium in a recent issue of your magazine was of particular interest to me in view of his reference to the use of cadmium for the manufacture of cadmium lithopone.

Some results from an investigation made into the commercial possibilities of producing that pigment and deductions therefrom may be of interest and value.

Cadmium lithopone in which the zinc of standard commercial lithopone is replaced by cadmium shows good covering properties and a high tinting strength—an admixture of only 5 per cent cadmium lithopone with 95 per cent standard lithopone, giving a pleasing and distinct cream yellow when rubbed out in oil.

The manufacture of cadmium lithopone follows in general the procedure for zinc lithopone, though certain precautions not required when zinc is used are necessary, and under control of the operator considerable variation in the shade and depth of the yellow color of the product may be obtained.

The use of metallic cadmium as a raw material is to be avoided, however; technically, because of the difficulties in getting it into solution as pure sulphate; commercially, because of its high cost, and Mr. Hanley's article seems to point the way to escape therefrom.

In the process of separation of the associated elements

he obtains a combined solution of zinc and cadmium sulphate apparently of approximately equal parts from which cadmium sponge is made for re-solution as sulphate relatively free from zinc.

The presence of thallium in small quantity has not been found detrimental and its removal would probably be found unnecessary.

The cost of the cadmium in the sulphate solution is, in the absence of cost figures, difficult to determine, but analysis of the methods, apparatus and man-hour figures, and with allowance for overhead and profit in the quoted prices, indicates that not more than 40 per cent, or less, of the present selling price of the metal, \$1.40@ \$1.50, or, say, 60c., is a liberal figure at which the charge for cadmium should appear in the lithopone product. At the present prices for acid, barytes, coal, etc., and labor, and taking cadmium at 60c., the cost figure for cadmium lithopone works out at 29c. per lb., including a 20 per cent profit. This figure is on the basis of using the sponge cadmium.

On account of the high strength of cadmium lithopone and because in most commercial uses it probably would be mixed with a large proportion of zinc lithopone or other white pigment, lithopone made from the equal part sulphate solution would have color and other values probably sufficient for many purposes.

Where cadmium lithopone is thus made in combination with zinc lithopone and by reason of lower cost chargeable to cadmium than the above 60c. figure and by reason of greater bulk, the product should cost appreciably less per pound than the above 29c. figure for the cost of cadmium lithopone content of the combined zinc and cadmium lithopone.

Given a source of cadmium from which the sulphate may be made at a cost comparable with the above example, the profitable manufacture of cadmium lithopone is indicated, especially when carried out in connection with other allied manufacture, as would probably be the case.

PAUL W. WEBSTER.

Perry & Webster, Inc.,
New York City.

The Metric System and Religion

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with profound wonder, mixed with something else, the reprints of certain articles on the chemistry of embalming which you printed some time ago. Now I pick up the latest issue of CHEMICAL & METALLURGICAL ENGINEERING and note the story entitled "Easy Money From Peat." It is certainly a modern miracle. My boyhood was spent up in the State of Maine, where the original demonstration (for public consumption) of easy money by the economical separation of gold from sea water was staged. But this was as nothing compared with these up-to-date superscientific wonders.

These things prompt me to send you the following letter on the dangers of our country adopting officially the metric system. It was written to the editor of one of our metropolitan daily papers and printed on the editorial page.

Your correspondent suggests as a topic of conversation the metric system and informs your readers that Congressman Britten has introduced a bill into Congress for the general use of the metric system by this country ten years after passage.

An attempt was made several years ago to introduce the metric system in this country, but it was not successful. The American engineers rejected it.

Aside from the fact that the metric system is based upon an unscientific premise and that in addition there

is a miscalculation in the length of the meter itself, this system is foreign to the Anglo-Saxon race, being Roman (French) in its origin. It was an element in the French attempt to eradicate religion from the earth and to introduce a system of atheism. It is an infraction of the Mosaic system of measurement, which is definitely correlated to and preserved in the Anglo-Saxon inch. It is not recognized either in America or in Britain.

It would seem that there are other methods besides physical occupation of territory in this hemisphere of attempting to attack and to violate the Monroe Doctrine, and the effort to introduce the metric system in this nation (America) is one of these "other" methods. It will not succeed, since God is keeping watch over His own. The eyes of all Americans should be wide open to these insidious attacks upon our institutions.

"In God We Trust."

Its reading has made me sad. I have an inherited religious tendency and was brought up to have a feeling of reverence for sacred things. In fact I am actually a member of that Church now most vigorously urging the passage of more of our well-known "blue laws."

But now my conscience troubles me. Every time I have sat down before my chemical balance with its set of metric weights I have committed a sin in comparison with which kneeling before a heathen idol in a Chinese joss house would be a mere peccadillo. I must make a change in my manner of living. Instead of weighing out one gram of potassium iodide I shall hereafter

weigh out $\frac{1000}{28350}$ of an ounce. I write this in fractional form for fear that perhaps even the mere use of the decimal point itself might be an infraction of the Monroe Doctrine, and I have reformed.

Little Falls, N. J.

R. R. HENDERSON.

To Prevent Use of Industrial Alcohol as Intoxicating Beverage

To the Editor of Chemical & Metallurgical Engineering

SIR:—This office is very much interested in the matter of the use of denaturants or repellent substances which may be added to completely or specially denatured alcohol in order to guard against the accidental or willful use of such alcohols for intoxicating beverage purposes, particularly in shops and factories.

There are a number of reasons why it would be inexpedient to require the addition of the particular substance which you call attention to—that is fluoresceine—for this purpose. The color imparted on dilution of an alcoholic solution of this substance might be objectionable to a number of manufacturers who use completely denatured alcohol or some of the widely used special formulas, such as specially denatured alcohol formula 1 or formula 2-B.

The voluntary addition of fluoresceine to a factory stock of completely denatured alcohol or specially denatured alcohol where the fluoresceine itself is in nowise objectionable as an added ingredient would seem to be highly desirable. The dilution with water of the neutral or slightly alkaline solution of fluoresceine produces an intense yellowish-green fluorescence which is practically transparent with transmitted light but markedly opalescent with reflected light. When this solution is slightly acid, however, the dilution with water produces very little change.

The addition of any substance to a denatured alcohol that would cause, upon dilution to potable proof, a condition repellent to the eye is of considerable value in protecting the alcohol from possible beverage use.

Bureau of Internal Revenue,
Washington, D. C.

JOHN F. KRAMER,
Prohibition Commissioner.

Western Chemical & Metallurgical Field

Southern California Edison Co. Granted Permit for Colorado River Power Development

The Federal Power Commission has granted the application of the Southern California Edison Co. for a preliminary permit to develop 2,500,000 hp. from the waters of the Colorado River. This is one of the largest developments that have been contemplated under the new water-power bill.

Some of the possibilities of the project may be gathered from the fact that the area that may be served with power includes the entire states of Arizona, Nevada and Utah, more than half of Colorado and New Mexico and three-quarters of California, with additional areas in Idaho, Wyoming and Mexico. The total power that may be developed is estimated at 4,350,000 hp.; about three and a quarter million acres of land can be irrigated and over 400 miles of the river will be made navigable. The Colorado River is the second in the United States in size, having a drainage area of 250,000 square miles and an annual run-off of sixteen million acre-feet. It is proposed to build a storage basin holding about forty million acre-feet which will impound 93 per cent of the run-off. About 35 per cent of the power will be used for railroad electrification; the remainder will be available for agricultural and industrial uses.

Production of Metallic Tungsten at Keeler, Cal.

During the war the several tungsten mines near Bishop, Inyo Co., Cal., were comparatively heavy producers of scheelite, but the mines have been idle since the armistice. An estimate of the capital invested for mine development and milling machinery is \$600,000. Some of those financially interested in the tungsten mines also have an interest in a soda ash plant on Owens Lake, about seventy-five miles from the mines at Bishop, and it was decided to experiment with the production of metallic tungsten, using soda ash and scheelite concentrates as the raw materials. A method has been developed by Cooper Shapley, general manager of the Round Valley tungsten mines, that produces a high-grade product at a very reasonable cost. An analysis of the metallic tungsten produced is:

	Per Cent		Per Cent
W	98.00	P	Trace
C	0.30	Cu	None
Fe	0.29	S	None
SiO ₂	0.03	WO ₃	None
Mo	1.25		

An experimental plant treating 25 lb. at a charge was built and an outline of the operation follows: The correct amount of trona, a crude soda gathered from the shores of Owens Lake at a cost of \$3 per ton, is mixed with the scheelite concentrate in a ball mill, the batch transferred to a firebrick crucible and melted with crude oil fuel, the flame striking directly on the charge. When the melt is quiet, the charge is tapped, the molten material flowing directly into a small Pachuca tank nearly filled with water. The water is agitated violently by compressed air during the pouring of the charge and for an hour in addition. The action of the water on the molten sodium tungstate shatters this material so that it will all pass a 20-mesh screen and the sodium

tungstate is easily and completely dissolved. The charge from the Pachuca is transferred to a redwood filter tank having a filtering medium of coco matting and canvas. The filtrate runs to storage tanks through a small filter press having filter paper between the plates. An absolutely clear solution results and, as the amount of insoluble matter is small, the press is cleaned only at rare intervals. The material in the filter tank is washed several times and the wash water returned to the Pachuca tank to be used for the next melt.

To precipitate an easily filterable tungstic oxide the solution is brought to boiling by means of steam coils placed directly in the solution and the boiling solution is transferred to stoneware crocks. The crocks are jacketed for hot water and contain enough hydrochloric acid to precipitate the tungsten as oxide. (About 3 per cent of nitric acid is used with the hydrochloric.) If the solution is kept nearly at the boiling point the precipitate will be comparatively coarse grained and easily filtered.

The precipitated material is allowed to stand for an hour at a temperature close to 100 deg. C., and the clear, weak acid solution decanted and replaced with distilled water obtained from the heating coils. The precipitate is run into a flat-bottomed filter tank having a filtering medium of coco mat and canvas (protected with shoveling strips) and is washed repeatedly with distilled water. An acid-free product results containing about 45 per cent water, as determined by heating a sample to 500 deg. C.

The batch is then transferred to a wooden mixer similar to a butter churn, and the correct amount of gas-house carbon is added to reduce the tungsten oxide to the metal. After kneading for half an hour the mixture is transferred to fireclay crucibles and allowed to dry slowly, waste heat from the reduction furnace being used to dry the product completely. Any reduction in volume due to shrinkage during drying is made up with more dry material, and the crucibles are covered with a graphite lid, ground to fit.

Reduction is done in a special furnace which is operated continuously and reduces a charge in about four hours' heating at 1,250 deg. C. Fuel oil is used for heating the furnace.

The metallic tungsten is a lumpy gray mass that must be ground and screened, and packed in 100-lb. tins.

Alunite Deposits of Utah

Increasing interest is being taken by Eastern capital in the alunite deposits of Utah. Several large concerns are doing important work in the state, while others are planning activity. One of the most recent important occurrences in Utah alunite history is the incorporation of the Utah Alunite Refining Co.

The company's holdings of eight claims are located in Sevier County, about 150 miles south of Salt Lake City and about one mile from Vaca station, on the Marysvale Branch of the Denver & Rio Grande R.R. Four products are obtained—potash alum, potassium sulphate, aluminum oxide and aluminum sulphate. It is stated that there is abundant water for milling purposes.

Iron:Nickel Alloys

Brief Description of the Properties of Nickel Steels and High-Nickel:Iron Alloys, the Former One of the Earliest Alloy Steels and Now of Widest Consumption, the Latter of Remarkable Thermal and Electrical Characteristics

BY PAUL D. MERICA

Superintendent of Research, International Nickel Co.

ALLOYS of nickel with iron, including nickel steels, are commercially by far the most important alloys of this metal, and the range of compositions used is a very wide one—from the alloys of low nickel content, the nickel steels, to those containing 30 per cent and more nickel. These alloys were first discovered in meteorites and have never ceased to interest and puzzle investigators because of the unusual properties of the alloys containing from 5 to 40 per cent nickel.

Binary alloys of all compositions solidify as solid solutions which upon cooling suffer both phase and magnetic transformations of great scientific interest and technical importance. The constitutional diagram¹ of the nickel:iron alloys is given in Fig. 1. Without entering upon a detailed discussion of the constitution of these alloys, for which further references² should be consulted, it is observed that the addition of nickel to iron and steel immediately depresses the temperature of both the A_1 and the A_2 transformation and in addition increases the temperature difference or lag between A_{c2} and A_{r2} —i.e., the temperatures at which iron loses its magnetism upon heating and regains it upon cooling respectively. This temperature range between A_{c2} and A_{r2} , within which the alloy may be either magnetic or non-magnetic depending on whether it has been heated or cooled to that range, is widened from practically zero for pure iron to about 500 deg. C. for an alloy containing 25 per cent of nickel; at the same time the

magnetic transformation range is lowered to ordinary temperatures and below. With increasing nickel content the temperature range of magnetic transformation again rises and becomes quite narrow—i.e., there is little lag in the transformation on heating and cooling. Steels of the former group, containing from 3 to about 30 per cent nickel, have become known as irreversible steels, whereas those of higher nickel content are called reversible steels. Accompanying these magnetic changes which characterize reversible and irreversible steels are corresponding ones in other properties, such as thermal expansivity, elasticity, electrical resistivity, the thermal alterations of which are also reversible or irreversible depending on the composition.

The presence of carbon causes further complications in the properties and behavior of these alloys and will be considered only in connection with nickel steels of low nickel content.

NICKEL STEELS

Nickel steel was the fourth alloy steel to be introduced and was first described in some detail by James Riley.³ The general subject of nickel steels is too broad for anything but the merest sketch in this place and references should be consulted for further details.

The principal effects of the addition of nickel to steel are the following:

1. Nickel depresses the critical temperature ranges of steel, and according to the degree of such depression we may consider three groups of nickel steels—namely, pearlitic steels, which have normal transformation and heat-treatment or critical ranges and are similar to ordinary carbon steels in a general sense; martensitic steels, self-hardening but too brittle to be of any importance commercially; and austenitic steels, which are not susceptible to hardening by thermal treatment and may perhaps more properly be considered as ferronickel alloys containing carbon. The nickel and carbon content of the steel determines its inclusion in any one of the above groups; Fig. 2, according to Guillet, gives a classification of different compositions of nickel steels.

2. Nickel dissolves in the ferrite of steel and increases the hardness and strength without a corresponding loss of ductility. Thus Bullens⁴ states that the addition of each 1 per cent (up to 5 per cent) of nickel to steel of forging grades will, without loss of ductility, increase the tensile strength and yield point from 4,000 to 6,000 lb. per sq.in., in the natural (not heat-treated) condition. But it is in the heat-treated condition that the superiority of nickel-containing steels is most evident and of most commercial importance. This is illustrated from the following data collected by the Society of Autom-

Published by permission of the Director, Bureau of Standards.

⁴"Steel and Its Heat Treatment."

FIG. 2. CONSTITUTION OF SLOWLY-COOLED NICKEL STEELS (GUILLET)

tive Engineers showing a comparison between the tensile properties of a 0.40 per cent carbon steel without nickel and the same with 3.5 per cent of nickel in the heat-treated condition:

Analysis	Yield Point, Lb. per Sq. In.	Tensile Strength, Lb. per Sq. In.	Elongation in 2 In.	Reduction of Area
0.40 per cent carbon...	53,000	90,000	25	62.5
0.40 per cent carbon, 3.5 per cent nickel...	83,000	108,000	25	66

3. Nickel exerts an influence on the grain size of ferrite and pearlite, tending to produce a finer grain structure and finer pearlite, shading into sorbite. In the same sense it diminishes the rate of grain growth within the temperature ranges for heat-treatment, and thus minimizes the danger of overheating.

4. The structural effects of nickel noted above make a nickel steel (2 to 3½ per cent Ni, 0.10 to 0.20 per cent C) invaluable for case-hardening and superior to carbon steels in uniformity of zone of carburization and in mechanical properties of the core after heat-treatment.

The beneficial effects of nickel upon steel are intensified by the presence of other elements, particularly chromium; and chromium:nickel steels are perhaps more widely used today for heat-treated forgings for automobiles and other construction than are the straight nickel steels.

The following grades of steel are in most common commercial use:

(a) *Structural Steel With 3½ Per Cent Nickel:*

This is the oldest and best-known composition and constitutes the bulk of commercial nickel steel produced today. Its composition will average nickel, 3.0 to 3.5 per cent; carbon, 0.20 to 0.40 per cent. It is usually made in the open-hearth furnace and is used both in the rolled or forged condition and after heat-treatment.

It is much used for rolled structural shapes in construction of bridges and similar structures. It has also been used in the form of rails, although its economy for this purpose has not been satisfactorily demonstrated. In the heat-treated condition it is used for gun, engine and locomotive forgings, as well as for many automobile parts in too severe service for ordinary carbon steels. The average mechanical properties of this composition of steel after quenching in water from 1,400 deg. F.

(760 deg. C.) and drawing at various temperatures are shown in Fig. 3.

(b) *Nickel:Chromium Steels for Heat-Treated Automobile and Other Forgings:*

These compositions constitute the most prominent group of "automobile" steels and are used for a great variety of parts and construction where high strength, toughness and ductility are required. Typical ranges of composition are given below:

	Chromium, per Cent	Nickel, per Cent	Carbon, per Cent
Low.....	0.5	1.5	0.20 to 0.50
Medium.....	0.5 to 1.5	1.5 to 3.5	0.20 to 0.50
High.....	1.5	3.5	0.40 to 0.50

The "low" and "medium" nickel:chromium steels are used primarily in the automobile industry for crankshafts, axles, driving shafts, spindles, bolts, etc., and for case-hardened pivot pins and cam rollers. The "high" nickel:chromium steels are used in the manufacture of heat-treated gears. The latter compositions are also the principal ones used in the manufacture of both armor plate and of armor-piercing projectiles. The mechanical properties of typical steels in the heat-treated condition are given in Figs. 4 and 5.

(c) *Nickel Steel for Case-Hardening:*

The principal properties of nickel steel which make it invaluable for case-hardening have been noted above; in addition there exists the possibility for high-nickel steels (nickel 5 to 7 per cent) of obtaining air-hardening or self-hardening case-hardened surface layers together with a tough pearlitic core. Typical compositions used for case-hardening are given below:

Low nickel:	Per Cent
Nickel.....	1.5 to 3.5
Carbon.....	0.10 to 0.20
High nickel:	
Nickel.....	5 to 7
Carbon.....	0.10 to 0.15

(d) *Mayari Steel From Cuban Ores:*

This is a natural alloy produced in the blast furnace and open-hearth furnace; it has been used principally in the form of rails and track bolts. Its composition averages nickel, 1.0 to 1.5 per cent; chromium, 0.20 to 0.70 per cent.

(e) *High-Nickel Steels:*

Such compositions as the following are termed perhaps more properly "ferronickel alloys": nickel, 25 to

FIG. 3. PHYSICAL PROPERTIES OF 3½ PER CENT NICKEL STEEL FOR STRUCTURAL PURPOSES AFTER VARIOUS HEAT-TREATMENTS

10 per cent; carbon, 0.3 to 0.5 per cent. They are austenitic and do not respond to usual heat-treatments; they are, however, naturally quite tough and strong, have a low thermal expansivity and are very resistant to corrosion in air, fresh or sea water. They are much used for gas engines, valves and spindles, for ignition and boiler tubes, for valve stems on sea-water pumps. The alloys may be rolled and forged, but are not so readily machined as ordinary steel. They will have the following average tensile properties in the natural state:

	25 to 28 per Cent Nickel, 0.3 to 0.5 per Cent Carbon	30 to 35 per Cent Nickel	35 to 38 per Cent Nickel
Tensile strength.....	85,000 to 92,000	85,000 to 95,000	100,000 to 115,000
Yield point.....	35,000 to 50,000	40,000 to 50,000	64,000 to 78,000
Elongation in 2 in....	30 to 35 per cent	30 to 40 per cent	25 to 35 per cent
Reduction of area....	50 to 60 per cent	40 to 60 per cent	50 per cent

The alloys containing about 25 per cent of nickel are much used for electrical resistance wire, in the construction of rheostats and electrical heaters. Table I gives values of the electrical resistivity⁵ and its temperature coefficient⁶ for binary alloys of nickel and iron.

The section given below on "Alloys for Electrical Purposes" contains further information on this application of the ferronickel alloys.

More recently Yensen⁷ has made a thorough study of the electrical and magnetic properties of iron: nickel alloys prepared by melting *in vacuo*. In Figs. 6 and 7 are reproduced some of his typical results.

Beginning at about 25 per cent nickel, the thermal

⁷Trans., Am. Inst. Mining Eng. (1920).

FIG. 7. ELECTRICAL RESISTANCE OF IRON:NICKEL ALLOYS (YENSEN)

expansivity of the ferronickel alloys at 20 deg. C. diminishes rapidly with increasing nickel content up to about 34 per cent; thereafter again increasing first rapidly and then more slowly to that of pure nickel. These curious changes are utilized in the manufacture of three patented alloys—invar, dilver and platinite—having respectively a thermal expansivity very low at ordinary temperature, nearly equal to that of glass and of platinum. Table III gives values of the thermal expansivity of ferronickel alloys.⁹

TABLE III. THERMAL EXPANSIVITY OF IRON:NICKEL ALLOYS

43.6	7.992 - 0.00273t	36.4 + 0.9 Cr	4.433 - 0.00392t

Invar contains about 36 per cent of nickel and has a mean linear thermal expansivity of approximately 0.000,001 per deg. C. between 0 and 40 deg. C. It melts at 1,425 deg. C., has a density of 8.0 g. per c.c. and an electrical resistivity of about 80 microhm-cm. It is very resistant to corrosion in water and may be immersed in it for days without the appearance of rust spots. Platinite is quite similar except that it has a thermal expansivity equal to that of platinum (approximately 0.00,000,9 per deg. C.) and contains about 46 per cent of nickel. Dilver has a thermal expansivity coefficient of 0.00,000,8 per deg. C. Invar, as well as the other alloys of similar character and composition, may be rolled, drawn and machined and is used for the manufacture of measuring tapes, length standards, instruments and chronometers of high accuracy for which temperature-length changes must be almost wholly eliminated. These and similar alloys are produced now in this country. For further information concerning invar, circular 58 of the Bureau of Standards should be consulted. Perhaps the principal present use for platinite is for the sealing in wire of electric lights.

German Potash Production

According to figures furnished by the German Potash Syndicate the sales of potash salts in 1919 reached a total of 4,159,227 metric tons, with 812,002 tons of potash. In 1918 the sales of the Potash Syndicate amounted to 4,840,934 tons of potash salts, with 1,001,664 tons of potash, showing a falling off in 1919 of 681,707 tons of potash salts and 189,661 tons of potash. In 1919 the sales of potash were less by 192,279 tons than those of 1917 and 298,367 tons less than the sales in 1913.

Among the various potash salts only carnallite, 30 per cent manure salts and sulphate of potash show a fair increase in sales for 1919, the last named going to foreign countries for fertilizing tobacco, cane sugar, fruit trees and potatoes. All the other salts showed decreased sales.

The first post-war shipments to Great Britain, United States and other overseas countries began in July, 1919. From this date on the foreign sales showed an increase. The sales of potash in 1919 were marked by a falling off in the following countries and in the following amounts as compared with 1918: Austria-Hungary 34,307 tons, Belgium 21,204 tons, Russia and Poland 5,171 tons, Switzerland 5,074 tons and Luxemburg 1,357 tons. On the other hand, increases for the same years are shown in the cases of Holland and the Scandinavian countries. Furthermore there appear as purchasers for the first time after the war the following countries: The United States with 70,128 tons, Great Britain with 10,278 tons, Spain with 358 tons and the remaining American countries with 1,648 tons.

As a result of the renewal of trade relations between Germany and the former enemy countries the sales of German potash increased from 141,947 tons in 1918 to 174,968 tons in 1919, an increase of 33,022 tons. This increase would have been greater had not the purchases of countries like Austria-Hungary, Russia and Poland fallen heavily behind preceding years. A further handicap to increased sales in 1919 is traceable to the difficulties experienced during that year in effecting shipments overseas due to the scarcity of shipping space.

The most noticeable decrease in the sales of German potash is found in Germany itself with a decline of 222,683 tons, of which the amount of 212,917 was classed as for agricultural purposes. However, as Germany in 1913 took 536,102 tons of potash for agricultural purposes, as against 608,766 in 1919, the year 1919 still shows a gain over 1913 in this direction of 72,664 tons or around 15 per cent.

The following table is a general report of the Potash Syndicate's import and export business for the years 1913 and 1919:

	1913 Tons	1919 Tons
Inland	604,282	637,032
Export	506,076	174,962
Total	1,110,358	812,001

Coconut-Oil Mill Situation in the Dutch East Indies

In an analysis of the coconut-oil mill situation in the Dutch East Indies, Trade Commissioner John A. Fowler points to the advisability of American manufacturers of oil-milling machinery developing the market which arises from the growth of the industry in these islands. Armour Fertilizer Works—II

Svenska Den System of Acid Phosphate Manufacture—Acid Pumping and Storage—Phosphate Rock Mill—Mixing Raw Materials to Produce Fertilizers for Various Soils—Mechanical Operations and Apparatus Employed in the Complete Modern Fertilizer Plant*

BY CHESTER H. JONES

FERTILIZER manufacture is carried on in the large building shown on the right in the above photograph and in the plan view Fig. 13. All raw materials except the acid are delivered from cars by way of the long platforms.

The operations consist of crushing and grinding phosphate rock, mixing ground rock with sulphuric acid to make acid phosphate, curing acid phosphate, removing hydrofluoric acid gas from the acid phosphate operation, accurately mixing and bagging other raw fertilizer materials. Electric current is distributed at 440 volts to the various motors in the plant through a large panel board located in the corner of the grinding room and so arranged as to meter the current consumed in the operation of each department. Trackage space for sixty cars is available, the tracks paralleling the shipping platform on both sides of the building.

The list of raw materials used in fertilizer blending

*For Part I see CHEM. & MET. ENG., vol. 24, No. 8, p. 333, Feb. 23, 1921.

are almost innumerable, but some of the more important ones are as follows:

Kainit from Europe. Potash content, 13 per cent.

Tobacco stems of high grade. Ammonia 3 per cent and potash 8.6 per cent.

Chilean nitrate.

Phosphate rock from the Columbia, Tenn., district with total P_2O_5 equivalent to bone phosphate of lime 72 per cent, iron oxide 2.8 per cent and Al_2O_3 2.8 per cent.

Sulphuric acid 53 deg. Bé.

Nebraska potash. K_2O content runs 20 to 30 per cent.

Muriate of potash from Europe. K_2O content is 50 per cent.

Tankage from the packing houses. Total P_2O_5 content is 9 per cent and ammonia runs 7 to 10 per cent.

Sulphate of ammonia. Ammonia 25 per cent.

Bone meal from Armour Glue Works. That known as 3-24 has 3 per cent ammonia and 24 per cent phosphoric acid; that called 2-27 has 2 per cent ammonia,

FIG. 13. PLAN OF FERTILIZER PLANT

27 per cent P_2O_5 . Raw bone meal ammonia 4.5 per cent, total P_2O_5 22 per cent. Manure salt. K_2O 20 per cent. Cottonseed meal. Ammonia 7 per cent, available P_2O_5 2.5 per cent and K_2O 1.5 per cent. Dried blood from Armour packing houses. In considering the successful outcome of a fertilizer - manufacturing enterprise it is well to remember that packing concerns have a distinct advantage in that they have an assured source of organic and animal ammonia.

ACID STORAGE AND HANDLING AT MILL

The 2-in. pipe line from the acid plant runs across the yard to the corner of the rock-grinding room, where acid is distributed by two Chemical Equipment Co. pumps shown in Fig. 14. These pumps are so connected that acid may be delivered to the mill storage tank for acid phosphate manufacture either directly from the acid plant, from the storage tanks, shown in Fig. 15, or directly from tank cars. Acid may also be delivered from storage tanks to tank cars or *vice versa* or it may be pumped from acid plant to outside storage tanks.

These tanks have no bottom outlet, but are emptied and filled through piping at the top. The centrifugal acid pumps accomplish the drawing up of the liquid from either tank cars or storage by means of the auxiliary priming tank shown in Fig. 14. The complete piping connections for this arrangement are shown in Fig. 16.

Engineers will realize that the lifting of liquids directly upward for a distance of 16 ft. where the pump intake

FIG. 14. ACID PUMPS AT FERTILIZER BUILDING

is not flooded directly from the source of supply is an innovation in centrifugal pumping practice.

ROCK GRINDING

The phosphate rock is delivered from box cars to the crusher room shown near the lower left hand, Fig. 13, where it passes through a Valke & Murdock crusher system to produce $\frac{3}{4}$ -in. size material and is delivered to the rock storage room. Storage capacity is about 3,500 tons.

The traveling crane delivers rock to overhead bins, which in turn feed to the grinding and pulverizing plant in the rock-grinding room. This department is equipped with one Raymond pulverizer and two Kent mills, all driven from a line shaft by a 200-hp. Allis-Chalmers motor. The rock is ground for 95 per cent to pass a 100-mesh screen and is delivered by elevators to the bins above the acid phosphate machinery. The material is handled through the mill system by screw conveyors and steel elevators made by the Weller Mfg. Co. Between 125 and 150 tons of rock are ground every twenty-four hours.

ACID PHOSPHATE MANUFACTURE

The Svenska Den system for making acid phosphate was brought over from Sweden in 1911, the Armour company purchasing both patents and machinery from the original owners. It has been in operation in a great many of the Armour plants since that time. While the methods of handling the material, particularly the operation involving the pushing of a den full of the newly mixed phosphate against the cutting apparatus, may seem unwieldy, nevertheless the system is efficient in actual operation. It is necessary for the green phosphate to cure over a considerable period and the action in the dens has a certain beneficial effect toward this process.

A glance at Fig. 13 will locate the machinery adjacent to the rock-grinding room with the two dens in dotted outline and the four silos adjoining. Fig. 17, a side elevation taken from the rock-grinding room, gives an excellent idea of the arrangement of the duplicate system of machinery, and Fig. 18 is an elevation of the left end of Fig. 17.

The pulverized rock elevator appears in the center of Fig. 17, delivering the product through a butterfly

FIG. 15. ACID STORAGE AND PIPING

FIG. 16. PLAN AND ELEVATION OF ACID-HANDLING CONNECTIONS

valve on the third floor to the screw conveyors of either unit, whence it is carried to the dust weigh hopper over the mixers on the second floor. The acid 53 deg. Bé. sulphuric acid is simultaneously drawn to the acid-measuring hopper from the tank on the third floor.

Each charge for the Steadman pan mixer consists of about 1,625 lb. of acid, basis of 50 deg. Bé., and a like

quantity of ground rock, or about $1\frac{1}{2}$ tons total charge to the batch. Considerable quantities of fume are developed in the mixing and subsequent operations which is principally produced from the action of the sulphuric acid upon the fluorspar in the rock giving off hydrofluoric acid and silicon fluoride. This is conducted through tarred wooden flues to a wood stave tower

FIG. 17. SIDE ELEVATION, ACID PHOSPHATE PLANT

FIG. 18. LEFT END ELEVATION, ACID PHOSPHATE PLANT

system outside of the building and absorbed in water. The exhaustor on the end of the line is also made from wood.

Figs. 19 and 20 show the Steadman mixers and connections for feed and fume removal. The floor in the foreground of Fig. 20 is the movable platform over silo 1, as will be later noted.

When the batch is finished the mixer is discharged to the den directly below. One den is charged while the other is discharging.

The dens are constructed of heavily reinforced con-

crete on the side walls and bottom and will hold about 40 tons of acid phosphate. On the rear end wall of each den is located the pusher plate, actuated by the pusher mechanism. The position of pusher plate shown on the right hand of Fig. 17, mezzanine floor, is maintained while the den is being filled from the mixer above. The front end wall consists of a movable steel plate set at an angle, as also shown, on the same den, completely closing the opening during the charging.

As soon as the den is completely filled this steel door is elevated out of the way by the drum gate hoist on the third floor and the den is ready for discharging. The cutting mechanism is next thrown into operation. This consists of steel link belts equipped with large cut-

FIG. 19. STEADMAN MIXER, SHOWING WOODEN FUME LINE

FIG. 20. MIXER IN OPERATION, SHOWING DRIVE

FIG. 21. RASPER AND DRIVE

ting wires, the whole covering the face of the material as exposed by the raising of the steel gate. This mechanism is indicated in dotted outline as belts running at approximately the same angle as the gates.

Simultaneously with the starting of the cutters, the pusher motors are thrown in and the pusher plate slowly moves forward, forcing the whole mass of material against the cutters as fast as they can operate to shave it away at the surface.

Left-hand den, Fig. 17, shows position of pusher plate when den is nearly discharged. The machinery which operates the pusher plate consists of four large threaded bars with driving nuts working on the order of a screw-jack. A rear view of the plate mechanism is shown in Fig. 18.

As the cutters shave away the wet packed material to a powder it falls into the boot of the acid phosphate

FIG. 22. CRANE HANDLING ACID PHOSPHATE TO STORAGE PILE

elevator, Fig. 18, whence it is delivered to the rasper chute.

RASPING AND AIRING

The rasper receives the damp phosphate and puts it through a further intimate mixing operation in much the same manner as the den cutters. The chute and rasper drive are shown in Fig. 21. The rasper is located between silos 1 and 2 as indicated in Fig. 13, and may be discharged to either silo. It will be noted on the left of drawing, Fig. 18, that each silo is covered by a movable platform while being filled. This forms a closed compartment from which the fumes and dust

are drawn to outside atmosphere by a Sturtevant exhaustor during the operation. The platform appears in the foreground, Fig. 21, one of the supporting car wheels showing on the left. When a silo has been filled the platform is moved away by motor drive and the material is removed to the curing piles in acid phosphate storage by overhead crane. Here it remains at least six weeks before shipment. About 50,000 tons is produced annually at the present time.

Fig. 22 is a view down one side of the fertilizer mixing plant from the silo platform with one of the two Champion 10-ton cranes delivering phosphate to the curing piles in storage. Fig. 23 shows a closer view in the

FIG. 23. MIXING PLANT

same direction with the crane in position to discharge a load to the mixing bins. Note industrial railway running along tops of bins and the two cars, Fig. 22.

MIXING FERTILIZER

The general layout of operations here differs from the usual principle of having the straight line flow of materials through the plant in that the work is carried out in three dimensions.

The crane is the key to the situation in that it both fills and empties stock piles from the top. The partitions or bulkheads for separating the various stock piles are

made up from 2 x 10-in. timbers laid flat and spaced with 2 x 4's on edge. (See Fig. 24.) This new system of bulkheading secures better ventilation of the piles and allows ready alteration in partition arrangements to suit changing conditions and quantities of materials. When it is desired to mix up a certain fertilizer the crane man is handed an approximate weight formula and proceeds to gather the ma-

FIG. 24. BAGGING MILL 3

materials from the stock piles in the material storage area, dropping them into the tops of the mixing bins as shown in Fig. 23, one kind of material to each bin. Some material is also delivered by the industrial rail-

FIG. 25. MILL 1

leased on signal, to secure a preliminary mixing on the belt. Entering the elevator boot at mill 1, mixed material is delivered to the Steadman shaker screens on the upper balcony (Fig. 25.) The fine material goes through to the mixing hopper shown suspended from the second balcony. The reject from the screen goes through the squirrel cage disintegrator, seen as a large revolving cylinder on the first balcony, and thence is returned to the shaker screen.

MIXING THE FERTILIZER AND BAGGING THE FINISHED MATERIAL

When the charge is completely screened and delivered to the mixing hopper it is released into the Steadman pan mixer. Here it is held until thoroughly mixed. This is the most important operation in the production of mixed fertilizers. The mixer discharges to the three bagging hoppers on the main floor. The finished material may either be bagged at the hoppers or returned to the floor as shown through the chute on the lower right. Here it is again picked up by the crane and conveyed to mixed material storage. The bagging mill is manufactured by the Atlanta Utility Works and is equipped with automatic scales.

Unloading mills 1 and 2 are simply elevator arrangements for receiving material from piles dumped into the boots by crane and conveying it to the cars on the industrial railway overhead.

Bagging mills 3 and 4 receive finished material from the mixed fertilizer storage piles by way of the crane and wooden bagging bins. These empty into an elevator hopper which feeds a shaker screen through inclined chute, upper left, Fig. 24. It passes downward through the shaker screen to the steel hopper directly below. Thence it is drawn off through the two bagging hoppers equipped with Sturtevant automatic scales.

The bagged fertilizers are stacked along the floors on each side of the building immediately accessible to the shipping platform. Elwell-Parker storage battery trucks are used for conveying the bagged material about

the storage and shipping platforms. Equipment for charging and maintaining the batteries is located next to the shop, Fig. 13.

AUXILIARY EQUIPMENTS

Completely equipped machine shop, electricians' shop, tool room and locker wash rooms for white and colored force are maintained in the fertilizer building. Every provision is made for taking care of the men. About 60 per cent of the personnel is colored labor. Fire protection is maintained by a Dayton-Dowd centrifugal pump rated 1,000 gal. per min. against 100 lb., with a full speed of 1,750 r.p.m. direct-connected to a 100-hp. 1,740 r.p.m. Northwestern Mfg. Co. motor, drawing its supply of water from a 200,000-gal. concrete reservoir.

The chemical laboratory occupies the top floor of the brick office building and is well equipped for both research and control work. Ten chemists make up the present staff.

CONCLUSION

Manufacturing plants, like men, have character, but the character of any plant is only a physical manifestation of the sum of human characters who carry on the daily operations. The designers, it is true, are responsible for the mechanical beauty of the process in all that the word means to the heart of an engineer, but the operators may mar or enhance its being. They alone are responsible for its becoming a marvelous living thing. If they do not put into the work that something we call morale or spirit, the total effect on the visitor is more depressing than an overgrown graveyard.

Those engineers who are privileged to observe the character of procedure of the Armour Fertilizer Works organization at Chicago Heights carry away an inspiration from both an æsthetic and economic viewpoint. The chemical engineers lay down alike the immediate and the new lines of work to follow and the common sense human touch carries it through.

Crisis in Swedish Tar Industry

The Swedish tar industry, which during the war reached considerable proportions, seems to be facing ruin, reports Consul Walter H. Sholes, of Goteberg. Of the about 900 factories of the country, not more than 100 are working, and these few are working under unfavorable conditions. Good wood tar, which before the war was sold at 30 to 35 ore per kilo (7.8 to 9.1c. per 2.2 lb.) now brings only 15 ore (3.9c.), while manufacturing expenses are estimated to be double. Factory owners have been forced to the unusual expedient of asking for a loan from the government. It is possible that this will appear before the coming Riksdag.

Production of Castor Beans in Java

Castor-bean production is now encouraged in Java states an issue of Holland's *East India*, the oil being already used by the natives, especially for the Battik textile industry. It has been found that the seed can be safely grown under copra trees, the yield per acre adding considerably to the native's profit on the copra. During the first half of 1920 exports of castor beans from Java amounted to 742,000 kilos (kilo equals 2.2 lb.), against 301,000 kilos for the corresponding period of 1919 and only 99,000 kilos during the first six months of 1918.

Macroscopic Examination of Metals

A Brief Statement of the Defects Which May Be Revealed by Visual Examination of Etched Smooth Surfaces of Steel and Other Alloys—Physical Unsoundness and Internal Strain May Be Detected by Special Methods

By HENRY S. RAWDON

Physicist, Bureau of Standards

THE term "structure," when employed with reference to metals and alloys, is used in a somewhat restricted sense. The metal microscopist ordinarily does not include in his definition of this term such characteristics as the minute crystalline structure, the arrangement of atoms and such other fundamental features of the structure of matter as may be revealed by suitably refined means. The term is used to include those features for which no refinement greater than that to reveal which the modern compound microscope is necessary. It should be borne in mind, however, that in a few special cases recourse must be had to very special means for suitably revealing the structural features of the metal.

MACROSCOPIC EXAMINATION

The study of the structure of any metal most properly begins with the macroscopic examination of the specimen—that is, with an examination which does not involve any magnification other than that obtained by the use of the simple magnifier. Although this survey is usually made for the purpose of revealing chemical non-homogeneity, generally by some suitable etching method, other important structural features are often revealed. The various features revealed by the macroscopic examination of metals may be summarized under the following types:

1. Chemical non-homogeneity, due to segregation, liquation, decarburization, cementation and similar causes. In wrought metals, lack of complete chemical homogeneity often serves the useful purpose of furnishing a record of the plastic flow of the metal during the various manufacturing operations. This is generally revealed by etching.

2. Crystalline heterogeneity due to rate of cooling and to local variations in the cooling. Local overheating may also contribute to this. Etching with ammonium persulphate is admirable for both steel and copper alloys.

3. Mechanical non-uniformity; presence of internal stresses. When the condition is very severe it may be revealed by deep etching with mercury solutions for copper alloys and concentrated acids for steels.

4. Physical unsoundness, blowholes, porosity, "flakes," internal discontinuities, etc. X-ray and the magnetic examination in addition to visual examination may be used to show such features.

CHEMICAL NON-HOMOGENEITY AND CRYSTALLINE HETEROGENEITY

One of the most serious and most common of the defects of alloys revealed by macroscopic examination is the lack of chemical homogeneity. Such variations in composition may be brought about in the material intentionally as, for examples, in case-hardened steels, partially malleable cast iron, and similar products, in which case it is hardly to be classed as a defect. In the greater number of examples by far, however,

chemical non-homogeneity represents an undesirable state resulting from conditions of manufacture, such as segregation and liquation. Such conditions often are so pronounced that they persist in the metal throughout the different treatments, both mechanical and thermal, that it received and so appear in the metal in its finished state. They may thus serve the useful purpose of furnishing a record of the plastic flow of the metal during the various manufacturing operations. Variations in the chemical composition of any alloy quite generally result in a differential attack of the material when it is subjected to the action of a corrosive or etching reagent of any kind. The greater the difference in composition in different portions of the metal the more pronounced are the relative differences in the etch-pattern which results.

GENERAL METHOD OF USING REAGENTS

Table I gives the more commonly used etching reagents for macroscopic examination of steel. Precautions in the manipulation may be as follows:

The specimen, which has been sectioned and roughly polished, carefully cleaned free from oil marks or fingerprints by washing in alcohol or gasoline and then dried, is immersed in the solution, polished surface up. Care must be taken that the solution quickly covers the entire surface, that no air bubbles are entrapped and that the liquid is agitated gently; otherwise queer misleading markings on the etched surface may result. If desired, the surface of the metal may be rubbed with a little emery flour on the tip of the finger washed with water and immersed while still wet so as to promote the even flow of the etching reagent over it.

Etch patterns produced by a prolonged attack by a dilute acid are often much less sharp and distinct than one produced in the same material by a rapid attack by a concentrated acid. A prolonged etching—for example, four or five hours—in 5 per cent alcoholic solution of picric acid is often very useful, however. The deeply etched specimen may be used for producing a permanent record by inking the face with printer's ink and making a print on paper.

SULPHUR-PRINTING

The distribution of sulphur is usually shown by the so-called sulphur-print method. The steel specimen is sectioned and the surface, after being smoothed off with a file, is pressed firmly against a sheet of photographic paper which has been moistened with a dilute sulphuric acid solution. Two c.c. concentrated acid in 100 c.c. water is the concentration generally used, though in many cases a more dilute one may be used to advantage. Particularly is this the case with metal very high in sulphur and also for very large specimens where considerable time is needed for placing the paper in

TABLE I. COMMON ETCHING REAGENTS FOR STEEL MACROSTRUCTURE

Name	Composition	Special Manipulation	Remarks
Heyn's.....	10 g. $\text{CuCl}_2 \cdot 2\text{NH}_4\text{Cl} + 2\text{H}_2\text{O}$ in 120 c.c. water.....	Copper film removed by wet cotton swab.....	
Iodine.....	10 g. I, 20 g. KI, 100 c.c. water.....		Markings not so clear as with Heyn's.
Concentrated acids.....	Conc. HCl Conc. HNO_3 in equal parts water..... 20 c.c. conc. H_2SO_4 in 100 c.c. water.....	At 100 deg. C..... Often used at 60 deg. C.....	
Ammonium persulphate....	1 or 2 g. $(\text{NH}_4)_2\text{S}_2\text{O}_8$ in 10 c.c. water.....		Excellent for crystalline heterogeneity. Also for copper alloys.
Mercuric chloride.....	10 g. HgCl_2 , 20 c.c. 1.12 HCl , 100 c.c. water.....	Dip thin silk in reagent and spread silk over metal.....	
Stead's.....	10 g. CuCl_2 , 40 g. MgCl_2 , 20 c.c. conc. HCl ; alcohol to make 1,000 c.c.....		
Le Chatelier.....	100 c.c. 95 per cent alcohol, 10 c.c. water, 1 g. CuCl_2 , 0.5 g. picric acid; 1 to 3 c.c. conc. HCl		

position. "Matt-finish" paper should be used. It is extremely difficult to prevent glossy paper from slipping on the metal surface, in which case a blurred print results. A fine polish of the surface such as is essential for microscopic examination is not necessary nor desirable for sulphur-printing. Very clear prints can be made on surfaces finished with a medium-fine file. Bromide paper or any of the common developing photographic papers may be used. By the use of a suitable press, prints which are as clear and definite as the photographs of the etched surfaces may be obtained.

The work of Le Chatelier and Bogitch¹ indicates that the darkening of the sensitized surface of the photographic paper is due to the action of the acid upon the sulphur alone and not to the combined action of sulphur and phosphorus, as was formerly generally supposed. The assumption is always made, however, that any non-homogeneity which may exist for the other metalloids, besides sulphur, occurs under the same conditions as does that of sulphur and that the distribution of sulphur recorded in the sulphur-print is an index of the distribution of the other constituents of the steel also.

For revealing the macrostructural features of brasses, bronzes and similar alloys of high copper content, an aqueous solution of ammonium persulphate is very often employed, although an acidified solution of ferric chloride or an ammoniacal solution of copper chloride may be used with very good results. The relative size and arrangement of the crystals are the features in which one is most interested—that is, in addition to the matter of soundness in the case of castings. In this case, however, an etching is usually unnecessary.

The reagent commonly employed for etching aluminum and its alloys for revealing the macrostructure is an aqueous solution of sodium hydroxide (approximately 10 per cent). It is customary to heat the specimen in the solution until the surface is sufficiently etched. A combination of alkali and hydrofluoric acid etching has been highly recommended by Carpenter.² The specimen is etched in an alcoholic solution of sodium hydroxide to remove the "flowed" surface metal. When the surface has been faintly etched, the sample is transferred to a dilute aqueous hydrofluoric acid solution (1 or 2 per cent) and allowed to remain until the etching is complete.

The occurrence of minute pores or intercrystalline cavities in castings of light aluminum alloys is a matter of grave importance. Their presence can often be detected in suspected metal by immersing a polished

specimen in alcohol colored with picric acid or some other brightly colored dye. The specimen, after rapid washing to remove all traces of the dye on the surface, is dried and allowed to stand in a warm place. The porosity of the metal is often indicated by the appearance of colored spots on the surface as the colored alcohol evaporates from within the internal cavities in which it was inclosed.

PHYSICAL UNSOUNDNESS

Much of the evidence of this phase of the structure of metals is furnished by a simple visual examination. In case the unsoundness is of a minute character, the method described for aluminum may be used. In other cases very special means must be used. If the surface of the specimen is carefully machined, a very light finishing out with a very sharp tool being made, evidence as to the *true* state of the soundness of material is often made available—information can be obtained in almost no other way. The ordinary methods which involve polishing and etching exaggerate the features of unsoundness to a considerable degree. In many alloys and metals which are rather coarsely crystalline careful machining is often sufficient also to reveal the structure of the material to a very surprising degree.

An examination by means of X-rays is often of value if the specimen is not too large. The features revealed by this method of examination are primarily those

FIG. 1. SECTION OF A 1-IN. MANGANESE BRONZE ROD ETCHED WITH AN ACIDULATED AQUEOUS SOLUTION OF MERCUROUS NITRATE. $\times 1$

which result from considerable differences in density, hence it is of great value in locating internal cavities and similar flaws. Ordinary segregation cannot be revealed by this means, although it has been successfully used in detecting such features of composition as resulted from the addition of a lead alloy for filling cavities in light aluminum castings. Specimens of steel to be examined by this means should not exceed $\frac{1}{2}$ in. in thickness. As a general rule, the thicker the specimen the more pronounced must be the defect in order that its presence can be revealed by this means.

For the detection of surface cracks such as may be produced by hardening by quenching and similar operations upon steel, a magnetic method will be found very useful. The method is particularly valuable for

¹H. Le Chatelier and B. Bogitch, "Macrographie des Aciers," *Rev. Met.* vol. 16, p. 129, 1919; *CHEM. & MET.* vol. 23, p. 383, Sept. 1, 1920.

²H. C. H. Carpenter and C. F. Elam, "Crystal Growth and Recrystallization in Metals," *J. Inst. Metals*, vol. 24, 1920.

revealing them in an early stage in the shaping of a piece—for example, precision gages and similar pieces which must be ground to size—so that defective specimens may be discarded without much expenditure of wasted effort. The roughly polished specimen is magnetized and then immersed in a light oil containing very fine iron dust in suspension. Kerosene and “cast-iron mud” such as is obtained from lapping disks may be used.

The iron particles bridge across any slight discontinuity in the surface of the specimen and locate very accurately the system of surface cracks. The excess of iron dust may be removed by bathing the specimen in alcohol or clean kerosene. The method has also been successfully used for the detection of internal fractures in wrought steel parts.³

MECHANICAL NON-UNIFORMITY

The examination of metals for mechanical non-uniformity—i.e., for the presence of internal stresses of high magnitude which may later lead to serious deterioration—may be noted here. Fig. 1 shows a portion of a cold-worked rod of manganese bronze which

FIG. 2. HARDENED STEEL BALLS WHICH SPLIT OPEN WHEN DEEPLY ETCHED WITH CONCENTRATED HYDROCHLORIC ACID. $\times 2$

has been immersed in a solution of mercurous nitrate acidulated with nitric acid. The cracks which were formed by the action of this reagent may be taken as an indication of what would undoubtedly have occurred spontaneously later in service.⁴ Materials which crack readily when treated in this manner can be shown by other means to be highly stressed internally, as has been described at length elsewhere.⁵

Steel parts such as balls and roller bearings which are very vigorously hardened indicate by their behavior upon etching in the proper manner that a similar condition obtains there. Fig. 2 shows several hardened steel balls which split when they were etched with hot concentrated acid; cold-rolled steel shafting will sometimes behave similarly when deeply etched in the same manner.

The cracking of the metals illustrated above when subjected to the proper etching reagents and the similar deterioration “season cracking,” which may occur spontaneously in service, are not to be regarded simply as a result of structural variations. However, the distortion of the structure in the cold-worked metals in which such conditions occur is very pronounced and undoubtedly is contributory in a very large degree to the unusual behavior of the metal.

Present Status of the Belgian Iron and Steel Industry

In spite of the active reconstruction work which has been carried on in Belgian metallurgical centers since the armistice, this industry is still far from obtaining its pre-war position, reports Trade Commissioner Cross, of Brussels. Particularly in the large plants centering about Liège, regardless of relative success in recruiting skilled labor and in recovering confiscated machinery, it has not been possible during the two years which have elapsed since the armistice to efface the damage done by the invading forces, since the resumption of production has been complicated by the necessity of diverting to repair work a relatively large proportion of the available help.

In the Province of Liège, out of 240 metallurgical plants of all sorts, ten are completely shut down, fourteen are producing less than 25 per cent of their 1913 quota, sixty-two are producing between 25 and 50 per cent, sixty-five between 50 and 75 per cent, and sixty-three are producing between 75 and 100 per cent. Only sixteen are giving over 100 per cent of the pre-war production.

The necessary capital for restoration and increased running expenses has been obtained to some extent through indemnities paid by the Belgian Government and largely by issues of new capital and debentures.

Out of fifty-one blast furnaces now existing in Belgium, twenty-one are in operation and seven others are substantially ready for firing. There were but twelve blast furnaces in operation on Jan. 1, 1920. Those at present restored have a capacity of 65 per cent of the 1913 production. Though there appears to be enough coke for all immediate needs, there is an appreciable shortage of enough coal of high volatile content for gas generators and Martin converters, and the plants which do not exploit their own coal mines are not able to accumulate large stocks.

Owing to the general destruction of rolling mills and the difficulty of renewing stocks of rolls, Belgian market offerings present a somewhat limited scope, but with the further progress of restoration a wider variety of products may be looked for.

Until the spring of 1920 the production of Belgian metallurgical plants was entirely engaged by the needs of domestic construction and by exports to northern France, and the competition for their products resulted in a considerable rise in prices, which reached its peak about the middle of May, 1920. From this date forward a slow and steady downward movement began. German competition is already making itself felt in finished steel products, such as bars, beams and rails.

The autumn of 1920 found the Belgian iron and steel industry producing 51 per cent of its pre-war production of pig iron, 69 per cent of finished iron, 54 per cent of steel ingots and 62 per cent of finished steel, thus indicating notable progress since the beginning of the year. The situation in fuel and raw materials has improved, especially on account of regular supplies of German coking coal and the operations of restored coke ovens.

Many plants aside from reconstruction work have modernized and extended their installations. The high prices, which rendered production extremely profitable, since the armistice have since May, 1920, given way before a slackening of demand. Furthermore, the problem of readjusting labor costs to falling prices creates an element of uncertainty in the present situation.

Relative Heat Conductivities of Some Insulating and Building Materials

BY JAMES J. LICHTIN

THE object of this investigation has been to determine by the so-called air box method the relative heat conductivities of materials used for insulation of apparatus, vessels, tanks, etc., used in the chemical industries or as building materials. Further, the aim has been to compare these conductivity values with the conductivity of a new porous insulating and building material "Porete," made of cement and sand, data of which have not been published before.

It was therefore necessary to conduct the tests of the different materials under equal conditions as nearly as

SCHEMATIC ARRANGEMENT FOR HEAT-CONDUCTIVITY TESTING

possible. A number of cube-shaped boxes were constructed of the different materials of practically the same dimensions, which were approximately 8 x 8 x 8 in. inside. The thickness of the walls was about 1 in. An electric lamp was used as a heating element inside these boxes. The electric current was regulated by a rheostat and measured by accurate voltmeter and ammeter.

The temperature inside was measured by two thermometers and outside by three thermometers, all located as shown in the accompanying drawing, and these thermometers were placed in the same relative position on each testing box.

The testing apparatus was set up in the basement of the laboratory, where the room temperature was fairly constant. No readings were taken during the first twenty-four hours in order to allow time for all conditions to reach an equilibrium. After this readings were taken about every two hours.

The conductivities K as shown in the accompanying tables in B.t.u. were calculated from the formula

$$K = \frac{3.415 \times B \times W}{12 \times A \times (T - t)}$$

where B is the thickness of the walls in inches, A the area in sq.ft., W the watts from the voltmeter and ammeter readings and $T - t$ the difference between the inside and outside temperatures as indicated by the thermometers. Area A was considered to be the mean between the inside area and the outside area of the box.

The thermal conductivity so measured is the quantity of heat in B.t.u. that flows through 1 sq.ft. unit area

HEAT-CONDUCTIVITY TESTING APPARATUS

of plates, through a unit thickness of 1 ft. having a unit difference of 1 deg. F. between its faces.

It is clearly seen from the table that the conductivity of Porete stands midway between that of gypsum and yellow pine. Comparing our conductivity values with those obtained at the U. S. Bureau of Standards,¹ where the plate method has been used in testing approximately the same materials, we note how nearly our figures agree with theirs, thus:

	Our Conductivity Values in B.t.u.	Density, Lb./Cu.Ft.	Conductivity in B.t.u. Equiv., U. S. Bu. of Stand.	Density, Lb./Cu.Ft.
Yellow pine....	0.0719	40	0.0799	34
Air cell.....	0.0335	13	0.0399	8.8
Cork board....	0.0277	11.7	0.0256	11

We are aware that the results thus obtained cannot be accurately compared with results of similar tests made under different conditions, because the conductivity K found in this way is not the heat transmitted only through the tested material of the thickness B , but it is the heat which passes through the layer of air from the inside thermometer bulb to the wall, hence through the wall, and thence from the outside of the wall to the outside thermometer bulb.

The results will be different from the results of tests where air contact has been excluded, and they will also be different from results of tests where fans or other devices have been used to keep the air in motion, thereby diminishing the resistance to the air entering into the wall of the material to be tested. However, as the figures arrived at are those under which the materials are used ordinarily as insulators or in building construction, they will give a good idea of the relative values of heat conductivity of the materials tested.

Possible Uses for the Spent Shale From Oil Shale Operations

BY KIRBY THOMAS
Consulting Engineer

ONE of the obvious problems in connection with the plans for the treatment of oil shales to recover oil and byproducts is the handling and disposal of the waste material. This waste amounts to from 60 to 80 per cent by weight of the material treated, depending on the amount of volatile hydrocarbons in the shale and on the amount of water, combined and uncombined. The bulk percentage is somewhat more than the weight percentage because of the expansion of the shale pieces and particles under the treatment process and because of the greater space necessarily occupied by broken or ground material of the physical character of shale.

DISPOSAL OF SPENT SHALE

In an operation having a throughput of a thousand tons daily the mere handling of the spent shale and its removal to a waste dump is a large mechanical problem. The cost of this feature of the operation must be a proportionately considerable item in the production costs. There exists also the necessity of providing suitable and adequate dumping sites. The factor of the cost of mining and breaking at the plant of this large percentage of waste material must be considered also, for the oil shale operations at best are in the class of the low-grade metal mines as to the relation of cost of operation and value of the product. In respect to the waste, the problem is somewhat similar to that with which the asbestos miners are confronted, only the value of the product is much greater in the case of the asbestos operations.

Fortunately the extensive oil shale deposits in Colorado and Utah, by reason of the usual cliff-like character of the shale beds which are likely to receive attention at the start and for a very long time, present very favorable conditions for the disposal of the waste, for gravity mill and waste dump sites generally can be selected and there is always plenty of outdoors for the unlimited extension of the dumps. In one instance it was proposed to place a treatment plant on a level site near the Grand River and it was planned to dispose of the waste by dumping it into the river. It was found that Uncle Sam and the state were likely to have something to say about such a procedure in the interests of control of flood waters for irrigation purposes and to protect the fish in the river. In the Eastern states the conditions as to waste disposal sites are not so favorable either from topographic considerations or from the standpoint of available dump area.

VALUE OF SPENT SHALE

Very little attention has been given to the waste disposal phase of the oil shale operations or to the investigation of possible uses for the waste material which would give it some value and aid in its handling and perhaps also contribute an important item to the aggregate of the products recovered from the shale by the processes proposed.

The waste shale is nothing more nor less than clay. Of course the different shale deposits vary somewhat in the general character of the mineral or inorganic material of which they are composed due to conditions affecting their origin especially as related to the character of the land surfaces from which in all cases the

material must have been derived in the first instance. The Colorado-Utah deposits have undergone no change through geological agencies such as result in the metamorphism and general rearrangement of the crystalline and molecular status of the original rock. In only a few localities have these beds been folded or even tilted since deposition. Such a condition does not prevail in some of the other shale deposits of the Western area. The Nevada deposits at Elko and the California deposits near Santa Barbara are steeply inclined and in some cases folded. Generally in these Western deposits there have been no changes or alteration through the heat agencies of volcanic intrusions or lava flows. Such conditions and relations prevail in a few Western localities, but these are not likely to be considered for the basis of operations now or for a long time to come.

It is to be noted that the recent flow of basaltic lava which covers some of the edges of the Green River shale beds of Colorado and which was once probably much more extensive has hardly changed the topmost layers lying in direct contact with the lava beds. The Eastern shale deposits are older than those of the West, being, in the Central states, mostly Devonian or belonging to the Mississippian member of the Lower Carboniferous. These are relatively undisturbed over large areas in Ohio, Indiana, Kentucky, Tennessee and Illinois and are free from the influence of all plutonic agencies. They have been somewhat tilted in some localities and in some cases there has been limited folding of such a character that it has changed the hydrocarbon elements of the shale into graphite. It is probable that some of the folding and orogenic movement has also resulted in the removal of the hydrocarbon material from the shale by influences of heat and pressure, or heat with pressure, and its transformation into the crude petroleum which is now being recovered by means of drilled wells tapping the natural catchment reservoirs in the overlying or perhaps also underlying strata. These Eastern shales are generally more indurated by reason of their greater age and perhaps the greater and longer pressure to which they have been subjected.

CHEMICAL COMPOSITION OF OIL SHALES

The shales everywhere vary slightly in their content of what may be called extraneous minerals. There is found a variation in the free silica and also in the silica which has come in by solution and percolation. There are small variations in the iron content and some also in the lime proportions. Sometimes other minerals, including the ores of the precious and common metals, are to be found in small amounts in the shale in irregular and limited localizations.

Yield of ammonium sulphate per ton of shale, calculated from small-scale distillation test, lb.....		4.32
Carbon in residue, per cent.....		13.02

A complete analysis of a sample of a Kentucky shale deposit in Powell County made by the Detroit Testing Laboratory is available. The analysis is given in the accompanying table.

This analysis is probably fairly typical of most of the Eastern shale deposits now under consideration. In the Western shale generally the percentage of the volatile matter is greater, but the ratio of the other elements in the residue is about the same judging from the small amount of precise chemical data at hand.

SPENT SHALE AS FUEL

After treatment the spent shale generally contains a considerable percentage of fixed carbon. This is called "coke" and it has a heat value which it is proposed to use as fuel in some of the process plans to supplement the non-condensable gas which is an unavoidable product of all of the retort operations. As this gas and the fixed carbon result from the imperfections of the applications of the method, they are a measure of the inefficiency of the process and it is small satisfaction to be able to convert them to some use of less value than would be the case if they had been recovered in the operation as valuable oil.

SPENT SHALE AS A NON-CONDUCTOR MATERIAL FOR ELECTRICAL APPLICATIONS

The spent shale with the fixed carbon—from 7 per cent up—has special qualities for use as a cheap material for a non-conductor for electrical applications. Experiments have been made in this use with reported good results. The material is molded wet and baked, or pressed into suitable shapes and forms. Similar experiments have been made with the untreated shale, and in consideration of the relatively larger carbon content, though not as fixed carbon, the results may be expected to be better than with the spent shale. This fact and the great abundance of the original shale make the effort in this line to find an outlet for the spent shale defeat itself.

SPENT SHALE AS A MATERIAL FOR MAKING BRICK

Practical tests of the availability of the spent shale for making brick for constructional purposes have been made with the material from the Colorado deposits. The results are very satisfactory, as might be expected. The brick have a greater strength for their size and weight than the brick from ordinary clay or slate. This point will give the shale brick a clear preference in an even competition aside from the probable lesser cost of the material for making brick, if the already mined and crushed waste shale is used. It is possible, too, that the physical condition of the clay from the spent shale and the effects of the preliminary heat-treatment may be beneficial and of advantage in its use for brick-making. This possible use for the waste will have a limited importance with the Western shale deposits mostly because of their remoteness from the best market for the brick. Of course tile and other similar products can be made from shale clay also, and these may furnish local needs in the West and have a better market as far as the Western operations are concerned.

In the East, where the shale deposits are situated in thickly settled regions, the making of brick affords an important and practical outlet for large quantities of the spent shale. In fact it is conceivable that some of the operations in Ohio and Indiana, as proposed, may find a profitable demand for their whole spent product

for making brick and tile and such products, which are used in great and increasing quantities at the present time.

USE OF SPENT SHALE IN THE CEMENT INDUSTRY

A use which has the possibility of taking care of a very large amount of the spent shale is connected with the plan to co-ordinate the shale operations with the cement industry. The waste heat from the cement kilns can be used to "boost" the heat for the oil shale retorts, and conversely the waste heat for the shale operation can be turned back to the cement kilns.

This idea has been embodied in patent 1,323,294, Dec. 2, 1919, taken out by Robert W. Lesley of Philadelphia. Mr. Lesley is a cement engineer of note and is largely interested in the cement companies of the East. The possibility of the making available of an essential ingredient of so low priced a product as cement at a lesser cost is conversely of more significance to the vast established cement industry than it is incidentally to the newer oil shale business.

It is probable that this relation is fully appreciated by the cement interests, which are now apparently quite well balanced in their competitive status. Generally it will be practicable to assemble the other materials for cement-making at the localities where the Eastern shale operations are proposed. These localities are chiefly in convenient positions to be correlated thus with the cement operations both as to assembling the raw materials and the distribution of the finished product. The projected shale operations in Kentucky are in the centrally located Powell County. The Indiana deposits of shale are in Floyd, Jefferson, Clark, Jennings, Scott and Jackson Counties. Other shale deposits are found in southern Ohio and eastern Tennessee, and in central Illinois. It is likely that they will be found in Pennsylvania and in western New York. This distribution is suggestive of a possible close interrelation between the shale industry and the cement industry if the mutual advantage as above discussed is proved by actual test on a large scale.

OTHER POSSIBLE USES FOR SPENT SHALE

A plan to mold the waste shale for railroad ties has been experimented with. It is claimed that a tie so made is strong and of course it is lasting. The claim is also made that a shale tie has a certain amount of elasticity which is lacking in a cement tie or in the sometimes used steel ties. The spent shale probably will soon make soil suitable for tilling, differing in this respect from most of the waste material from quarries and mines.

ECONOMIC ADVANTAGES RESULTING FROM THE USE OF SPENT SHALE

Taken in connection with the expectation that the shale will yield ammonia, and in some cases potash, in addition to the oil, the possibilities for useful applications for the waste are of great importance to the successful establishment of this new and needed industry in this country.

The determination of the practicability of these supplemental products from the oil shale will have the greater benefit to the Eastern shale deposits clearly and will go a long way, taken in connection with the collateral advantage in marketing the oil and other distillation products, in offsetting the lower oil yield of the Eastern shale—about one-half that of those of Colorado and Utah.

Manufacture of Synthetic Ammonia at Oppau, Germany*—III

Manufacture of Ammonium Sulphate, Ammonium Chloride and Ammonium Nitrate—Coke Plant, Power Stations and Other Supplementary Plants Required to Make the Oppau Works a Complete Entity—General Organization—Conclusion†

THE process employed at the Oppau works for the manufacture of ammonium sulphate with gypsum is based on the difference of solubility in water of calcium sulphate and calcium carbonate and is analogous to the Solvay process for the manufacture of soda. The process is protected by a French patent of the French Société Industrielle de Produits Chimiques.

The gypsum used is brought to the plant from the Neckarzümmer quarries by 108 special cars of thirty-four tons capacity.

The gypsum is first crushed to about fist size and charged into storage bins, whence it is carried by a bucket elevator to a belt conveyor leading to the hoppers of pulverizers. The pulverized gypsum is conveyed by an endless screw to a bucket elevator, which feeds the hopper of a recording automatic weighing machine. From this weighing machine the gypsum is carried into a hermetically closed reservoir provided with an agitator and into which is added water sufficient to prepare the required gypsum paste. The plant has three reservoirs of 3-m. diameter and 3 m. high. This paste can be stored in two reservoirs 5 m. in diameter and 5 m. high provided with agitators. The dust above the hoppers is collected by a ventilator and carried to a dust collector.

The paste is then brought into thirteen cylindro-conical reaction vats 3 m. in diameter and 1.5 m. high at the cylindrical part, and 1 m. high at the conical part. These vats are provided with belt-driven helicoidal agitators which are maintained at 45 deg.

The paste is fed through one pipe, the carbon dioxide through eleven pipes located around the cylinder and the ammonia through one pipe. The gases, after reacting, are brought by a pipe to a separator located above the cover. The separators are connected by a double piping, of which one is endless, the other leading to washing towers for the recovery of the ammonia. There are four such towers 12 m. high and filled with Raschig rings.

The circulation of the carbon dioxide is insured by a double compressor driven by a steam engine and by three ventilators driven by 150-kw. motors.

The contents of the reacting vats are led to two reservoirs 4 m. in diameter and 5 m. high provided with agitators and thence to three similar reservoirs in which the reaction is completed. The duration of the reaction is from nine to ten hours.

The mass is then sent to filtering vats. There are ten such vats 4 x 2 x 1.5 m., each vat containing twenty-eight 5-cm. thick plates, closed by filtering fabrics supported by sheet-iron plates provided with 5-mm. holes. Pipes from the bottom corner of the plates lead to a manifold which ends in three branches, each branch connected to a separator. The corners of the plates

diagonally opposite to the lower outlets are connected to a manifold vacuum duct. From the separators the filtrate is siphoned into reservoirs.

The calcium carbonate adhering to the plates is separated by the injection of compressed air and led into two separators 2.5 m. high and 1 m. in diameter, whence it is transported by an endless screw into two tanks 3 m. in diameter and 3 m. high. These tanks are emptied by a circulating jet of water from a centrifugal pump.

The ammonium sulphate solution is taken from the reservoirs, filtered and stored in reservoirs of 4-m. diameter and 5 m. high. The concentration of the solution is about 25 per cent. From these reservoirs the solution is brought into the concentration building, containing six double-effect evaporators of 2.5-m. diameter and 6 to 7 m. high, into which steam arrives at the middle part. The crystals formed are separated from mother-liquor in horizontal centrifugal dewaterers. The drained crystals are transported by belt conveyors to two coal-fired rotating drying furnaces. The dried crystals are then stored in storage bins 100 m. long, 50 m. high and 30 m. wide. Additional ammonium sulphate crystals are obtained by cooling the mother-liquors. These crystals are separated by filter presses or by draining, dried and stored in the above storage bins.

The Oppau works has a capacity for treating 1,000 tons of gypsum per day.

MANUFACTURE OF AMMONIUM CHLORIDE AND SOLVAY SODA

The preparation of ammonium chloride and sodium carbonate by the Solvay process (action of ammonia and carbon dioxide on salt) takes place in vats A (Fig. 15).

FIG. 15. SCHEMATIC ARRANGEMENT FOR THE MANUFACTURE OF AMMONIUM CHLORIDE

There are thirty-six brick-lined vats 3.5 m. in diameter, 1.5 m. high for the cylindrical part and 3 m. high for the conical part, and provided with helicoidal agitators driven by belts *b* and with cooling coils. The gases, ammonia and carbon dioxide arrive at the bottom of the vats through six pipes.

*From *La Technique Moderne*, November, 1920, pp. 449-460.

†For Parts I and II see *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 24, Nos. 7 and 8, pp. 305 and 347, Feb. 16 and 23, 1921.

The brine is prepared in a semi-cylindrical trough, decanted and stored in reservoirs 4 m. in diameter and 4 m. high, provided with agitators and with water and steam inlets. This brine is led to the reaction vats through *e* at the bottom of the vats.

The gases escaping at *f* are sent to two ammonia recovery columns. The paste leaves at the lower part of the vats at *c* and enters four tanks with filtering bottoms. Some of the crystals remain on the filter and are drained, the others are separated in rotary filters *F*.

The sodium bicarbonate crystals collected from the drainer and filter are conveyed to storage by a belt conveyor *t*.

The filtered solution is pumped into three 60-cu.m. reservoirs and thence into twelve double-effect concentrators. The concentrated product is sent into draining tanks. The drained crystals of ammonium chloride are conveyed to the storage and the solution is pumped into four reservoirs of 2 m. diameter and 6 m. high, where an additional concentration takes place with the separation by draining of another part of crystals, which are conveyed to the storage. The final solution is pumped into reservoirs 4 m. in diameter and 5 m. high.

The crystals of ammonium chloride from the storage are conveyed by belt conveyors and bucket elevators to rotary driers which are similar to those used for the drying of the ammonium sulphate crystals. The dried ammonium chloride is stored in storage bins.

The proportions of the reacting products are 78 ammonia for 269 salt. The action of the ammonia lasts from one and one-half to two hours and that of the carbon dioxide eighteen hours. The production capacity is 160 tons of ammonium chloride per twenty-four hours.

MANUFACTURE OF AMMONIUM NITRATE

Ammonium nitrate is manufactured by the direct action of nitric acid on ammonia. The reaction takes place in eight vats similar to those used for the manufacture of ammonium sulphate or ammonium chloride. The ammonia enters at the bottom through six pipes; nitric acid, from brick reservoirs, tarred inside, 4 m. in diameter and 3 m. high, is pumped into three stone-ware cylinders 1.5 m. in diameter and 2 m. high, whence it flows into the reaction vats.

The nitrate solution is collected in reservoirs 3 m. in diameter and 3 m. high, whence it is sent to evaporators.

FIG. 16. SCHEMATIC ARRANGEMENT OF COKE PLANT

These evaporators are tubular boilers, eight in number, of 2-m. diameter and 3 m. long. Steam at 12 kg. pressure circulates in the tubes and the boiler is under a vacuum of 60 to 70 cm. of mercury. The steam formed is received into a tubular condenser. The concentrated solution is received in reservoirs, whence it is taken to be treated for the production of nitrate in a manner analogous to that for the production of ammonium

chloride or ammonium sulphate, or mixed with a powdered salt, particularly potassium chloride, for the production of special fertilizers. This mixing takes place in flat vats provided with agitators. The paste formed is emptied by an endless screw and will be (the installation is not yet completed) conveyed by belt conveyors and bucket elevators to rotary driers and the dried product stored in two 100-m. long storage bins now under construction.

There is also an ammonium nitrate solution concentration plant consisting of two open vats heated by steam coils.

SUPPLEMENTARY PLANTS AT THE OPPAU WORKS

The Oppau works has been erected with the idea of being a complete entity and thus, besides the different departments described above, it also has all the needed supplementary departments such as manufacture of catalysts, coke ovens, motive power, coal-handling, water supply and laboratories.

MANUFACTURE OF CATALYSTS

The catalytic masses are manufactured in a separate building which contains crushers, mixers, pugmills and furnaces. The conveying is done by belt conveyors and bucket elevators.

COKE PLANT

The coke plant consists of two batteries of sixty-five ovens of the Collins system. Size of ovens, 8 m. long, 2.5 m. high, 0.40 m. wide (Fig. 16).

The coal is brought in by aerial transportation, discharged into hoppers *B* and bins *A*, whence it is charged into the furnaces *F*. The coke pusher *C* sends the coke to the quenching chamber *D* and hopper *E*, whence it is conveyed by aerial transportation to wherever needed.

The ovens of each battery have a common hydraulic main. The gas is treated for the separation of light oils. This takes place in two groups working in parallel, each group consisting of six towers 12 m. high, 3 m. diameter, which work in series. The gas then passes a rotary meter and is stored in a 10,000-cu.m. gas holder.

About 850 tons of coal are coked per twenty-four hours, giving about 650 tons of coke.

MOTIVE POWER

There are two electric power stations, one using producer gas, the other equipped with turbo-alternators. Both stations produce three-phase, 50-cycle, 3,000-volt current.

The lean gas power station comprises two Siemens-Schuckert 1,875-kw. alternators direct-connected to two 2-cylinder tandem Nuremberg gas engines and two 3,380-kw. Siemens alternators direct-connected to Thyssen gas engines. The exhaust gases from the Nuremberg gas engine enter tubular boilers generating steam at 4-kg. pressure, and the exhaust gases from the Thyssen engines enter tubular boilers generating steam at 12-kg. pressure and superheated to 270 deg. C. About 13 per cent of the lost heat is thus recovered, giving about 0.36 kg. of steam per kw.-hr.

The turbo-alternators power station comprises one Curtiss 6,250-kw. turbine with an A. E. G. (Allgemeine Elektrizitäts Gesellschaft) alternator, two Quelly turbines with Siemens-Schuckert 4,000-kw. alternators and one Brown-Boveri turbine with a 4,000-kw. Brown-Boveri alternator.

The boilers (Fig. 17) are formed of four horizontal parallel cylinders *A, B, C, D*. The cylinders *A* and *C* are connected by ten vertical tubes *F* and the cylinders *B* and *D* are connected by ten tubes *E*, which form a 60-deg. angle with the horizontal. Cylinders *A* and *B, C* and *D* are also connected respectively by two 25-cm. tubes *G* and four 36-cm. tubes *H*. Cylinders *C* and *D* are besides connected by three vertical tubes with drums *I*. The steam is superheated in a superheater consisting of coils. Lignite briquets are used as fuel and are fed by mechanical stokers *K*. Four groups of boilers are also arranged for firing with gas. The total heating surface is 17,785 sq.m. and the grate surface 355.7 sq.m. The production of steam is about one ton per hour per sq.m. of grate. The consumption of fuel is 2,400 tons lignite briquets per day, which is equivalent to 1,300 tons of coal.

Besides these two central power stations there are a number of steam engines and steam turbines installed separately in different buildings and connected to different machinery such as pumps, compressors and ventilators. These steam engines and turbines receive the steam from the central boiler room or from individual boiler rooms, using the hot gases from the different reactions in the respective buildings.

COAL HANDLING

On the average the plant uses over 2,000 tons of fuel per day, practically all of which is handled mechanically (only 5 per cent of the total power required is furnished by manual labor). The fuel arrives by barges on the Rhine River, and is unloaded by hoists running on overhead rails located parallel to the river. These rails *A* form a U with the two branches of unequal length. The short branch (450 m.) runs along the Rhine, the long branch (700 m.) runs along the fuel storage yard. The cars are hauled by a continuous cable manipulated from the cabin *B* (Fig. 18).

The unloading is done by three hoists *C*. Each hoist consists essentially of a beam *D* (Fig. 19) inclined at 46 deg., the lower part of which is jointed and kept in the dotted position when not working. A bucket *e* runs along the beam. The coal taken from the barge is emptied into hopper *F* after it has been weighed by an automatic weighing machine. From the hopper the fuel may be loaded into cars *W* running on rails to the desired place, or into buckets running on aerial transportation *G* which is provided with a series of switches (Figs. 20 and 21) for directing the disposal of the fuel in the buckets. The switching is done as follows: The aerial rails have side tracks, *H*₁ and *H*₂ connected to the main track by inclines, *K*₁ and *K*₂, and a series of pulleys *L*₁, *L*₂, *L*₃, for the driving cable. The pulleys are so arranged that under normal conditions the buckets when approaching the side tracks *H*₁, *H*₂ are detached from the main driving cable and by their own momentum run over the sidetrack and incline back to the main track, where they are again caught by the driving cable.

If switching is needed the bucket, instead of running back to the main track, is directed to the desired track

FIG. 17. ARRANGEMENT OF BOILERS, TURBO-ALTERNATORS CENTRAL STATION

branch and is pushed along this branch by manual labor until it is attached to the respective driving cable. *M* and *N* are transmission stations.

Along the other branch of the *U* there are five cranes *Q* and hoists *P* for loading the coal from the storage yard into bins running along the aerial transportation lines to wherever needed. By convenient switches the fuel can be directed to fuel storage bins located in different parts of the plant. Special switchings connect the main aerial transportation lines to the coke plant and gas producer buildings.

WATER SUPPLY

The plant consumes on the average 7,000 liters of water per second. This water is supplied from the River Rhine by seven centrifugal pumps driven by electric or gas motors. There are two water reservoirs connected to the river by two conduits respectively 1.70 m. and 1.10 m. in diameter. The water before being used is filtered through a 50-cm. sand layer in eighty sheet-iron vats of 15 x 3 x 1-m. dimensions. This filtering implies a loss of 2-m. pumping head, which is to be added to the 6-m. head required for supplying the plant. The size of the discharge pipes of the centrifugal pumps varies from 60 to 100 cm. according to the type of the pump. There are nine pumps, of which six are gas-motor-driven and three electric-motor-driven. All the water is first sent into a 1.3-m. diameter reservoir, whence it is distributed by three main branches to wherever needed.

LABORATORIES

Each department has its own laboratory where all the routine work analyses are made and in which there is besides a special personnel of chemists doing research work.

There is also a main laboratory directed by Dr.

Mittach, where fifteen to twenty chemists and fifty to sixty subordinates are employed for research work affecting the efficient operation and improvements of the general process.

FIG. 22. PLAN OF THE WORKS

The Oppau plant has a number of special shops for forging, turning, mounting, carpentry, building, etc., in which practically all the requirements of the plant can be taken care of. Only the heavy forgings and foundry pieces, electric motors, steam engines and gas motors are of outside make.

The entire works at Oppau employs about 5,000 men, of whom about 2,000 are employed in the shops.

GENERAL ORGANIZATION

The plant as shown in Fig. 22 occupies an area of about 800 hectares. Its construction was begun in 1912 and offered some difficulties owing especially to the small resistance of the soil. It was necessary to go to a depth of 17 m. to find a solid base for the foundations.

All the buildings are spacious, well lighted and ventilated. Pipe lines for gas, steam and solutions are laid all over the plant, some overhead and some underground. When the pipes are laid underground they are inclosed in easily accessible conduits.

The greatest care has been exercised to reduce the manual labor in all the plant to a minimum. All the shops are provided with cranes, electrically-driven hoists of appropriate power and strength. The transportation of the solid materials is made in special cars with automatic discharge or by belt conveyors, endless screws or bucket elevators. The fertilizer storage bins are provided with hoists on cranes which charge the material

onto belt conveyors. Sacking is done automatically and the weighing is made by recording automatic weighing machines.

All the manufacturing processes are carried out scientifically with the help of a series of measuring instruments. These instruments are connected to observation boards and are under the supervision of an able supervisor who can thus direct all the operations of a corresponding department. There are besides a series of recording instruments by which the superintendents can always judge of the work of his personnel.

The Oppau plant may be considered as a model of organization and this is apparent when it is considered that a plant of such size and capacity employs relatively a very small personnel (a total of 5,000, of whom 2,000 are employed in the shops only). There are about 500 superintendents and foremen and about sixty technical engineers.

As is generally the case in all German plants, all the em-

ployees, engineers and laborers alike, are given well-determined tasks and do not have access to other departments than their own unless they have special permit.

CONCLUSION

The cost of the Oppau plant was 300,000,000 marks (\$75,000,000 at pre-war exchange rates). It has a capacity of 300 tons of ammonia. (It is said that the Merseburg plant has a capacity of 900 tons of ammonia.) It is estimated that at pre-war prices the cost per kg. of combined ammonia was 0.70 mark, and it is not surprising that with such production costs it was very easy to compete with the Chilean and Peruvian nitrates and to make Germany independent of these natural supplies. It is to be taken into consideration that this low cost was made possible by the abundance of fuel and river transportation facilities.

The French are now working in quite a different direction from that of the Germans for the manufacture of synthetic ammonia for fertilizer purposes. Georges Claude is doing excellent work on dispensing with the use of the costly sulphuric acid for making ammonium sulphate fertilizer and instead he will use the now wasted byproduct of the Solvay process and produce an ammonium chloride fertilizer.¹

¹The characteristic distinctions between the Haber and the Claude processes for the production of synthetic ammonia were summarized in CHEM. & MET. ENG., vol. 23, p. 395, Sept. 1, 1920.

Molybdenum Steels*

Development of Molybdenum Steel in America—Early Experiments with This Element in Complex Alloys for Tools—Recent Successful Utilization in Mechanical and Structural Steels of High Strength and Great Adaptability

BY JOHN A. MATTHEWS†

IT IS twenty years since the writer made his first molybdenum steels and others were making them commercially five years earlier, but the prevailing opinion seems to be that molybdenum steels are new; from time to time the daily press speaks of important discoveries in Europe and intimates that American steel makers have much to learn in regard to alloy steels. The earlier experiments were largely confined to the use of relatively high percentages of molybdenum in tool steels and permanent magnet steels. Recent developments deal with the types of alloy structural steels used for airplane, automobile and other engineering requirements; in these, the molybdenum content is usually less than 1 per cent. The earlier types generally have been unsuccessful commercially, but the newer types of steels are becoming of increasing importance.

The war showed our dependence on foreign sources for alloying metals; molybdenum alone is widely distributed in the United States and seemingly abundant. Many deposits are now of commercial interest, owing to location and relatively small amount of ore available, but other deposits are being developed and a stable source of supply seems well assured.

In tool and magnet steels, it was early found that 1 part of molybdenum was equivalent to from 2 to 2.5 parts of tungsten. The permanent magnet steels investigated by Mme. Curie,¹ in 1898, contained from 3.36 to 4.05 per cent molybdenum; in 1902, Dr. E. L. French and the writer thoroughly tested steels containing from 2.0 to 4.0 per cent. These steels gave satisfactory tests for permanence, but were low in residual density and much more sensitive to hardening than the corresponding tungsten products. We discontinued work with them therefore, and have no advice that such steels have been used commercially here or abroad.

Prior to the development of the Taylor-White process and the modern high-speed steels, air-hardening steels were in general use. These were high in carbon and usually contained tungsten and chromium, the latter having replaced the manganese of the original Mushet air-hardening steels. Later, the tungsten content was frequently replaced by molybdenum. An air-hardening steel largely used had the following analysis: carbon, 1.75 to 2.00 per cent; molybdenum, 3.75 to 4.25 per cent; chromium, 3.75 to 4.25 per cent.

In the earlier years of the twentieth century, high-speed steels quickly displaced the air-hardening steels. Most of the manufacturers confined their efforts to tungsten-chromium combinations, but in

America determined efforts were made to use molybdenum instead of tungsten. At the time that one European metallurgist was claiming that steel containing over 6 per cent molybdenum could not be rolled, we were commercially rolling large quantities of a steel containing over 9 per cent molybdenum and had successfully rolled steel containing up to 15 per cent. The use of molybdenum above 6 per cent was patented,² as was the use of vanadium with either tungsten or molybdenum in high-speed steel.³ So far as molybdenum was concerned, the manufacture of these steels was discontinued almost before the patents had been allowed. One of these patents has now expired, but "discoveries" of chrome-molybdenum-vanadium steel and molybdenum-vanadium steel for high-speed purposes were recently announced. Both of these types of steels were made and abandoned nearly twenty years ago, as they were found, after very exhaustive experiments and tests, to be unsatisfactory both to manufacturer and in use. Occasionally these steels gave extraordinarily good service, as measured by the standards of that time, which were much below the present standards of the leading high-speed steels. However, notwithstanding the discouraging results of the earlier experiments, the writer has felt that some time we should have to use molybdenum, due to shortage of tungsten, or for other economic reasons, and from time to time during the past twenty years we have repeated our experiments in the art of manufacture. This helped us to overcome the earlier difficulties and objectionable features.

PRINCIPAL DIFFICULTY WITH MOLYBDENUM IN HIGH-SPEED STEEL

One of the principal difficulties with molybdenum in high-speed steel is its tendency to volatilize at the high temperatures necessary in the working and hardening of the steel. Indeed, it is possible to detect high molybdenum steels under the hammer by the light yellow smoke arising, which is probably due to the oxide of molybdenum.

After prolonged or excessive heating, a well-defined zone on the outside of the bars or tools is entirely different from the interior in structure, and as a result, finished tools, such as drills and cutters, which cannot be given the grinding permissible with lathe tools are not satisfactory; this has greatly limited the use of molybdenum high-speed steels. Both vanadium and cobalt have been tried in an endeavor to overcome this difficulty. Recently it was stated that cobalt and vanadium are "stabilizers" for molybdenum, but the writer has seen

*Paper read at the New York meeting A. I. M. E., February, 1921.

†President, Crucible Steel Co. of America.

²C. H. Halcomb: U. S. Pat. 722,504 (March 10, 1903).

³J. A. Mathews: U. S. Pat. 779,171 (Jan. 3, 1905).

no evidence to confirm these claims. On the other hand, molybdenum high-speed steel containing either or both of these elements has shown the defect in a marked degree. Some experiments now in progress promise more satisfactory results but it has not been determined whether our "stabilizer" in any way impairs the cutting qualities.

DEVELOPMENT OF MOLYBDENUM STEELS

Cobalt-molybdenum-vanadium high-speed steel was made and abandoned in America before the beginning of the European war, for it was found inferior to the regular tungsten-vanadium steel products with or without cobalt. After reading recently that cobalt-molybdenum-vanadium high-speed steel was the latest foreign contribution to tool-steel metallurgy, some of the cobalt-molybdenum-vanadium material made in 1914, some ingots made along similar lines in 1919, and some of the European steel were used in exhaustive and carefully conducted tests made by the Halcomb Steel Co., in which the leading brands of American and foreign manufacture were used. The molybdenum products failed to give satisfactory results and were rated much below the standard tungsten high-speed steels on the market today.

For the modern developments in the use of molybdenum, we are greatly indebted to C. Harold Wills, of Marysville, Mich. Having become convinced that there was abundant ore in this country, he experimented with molybdenum in a great variety of combinations. Much has been published regarding the physical properties and suggested types of molybdenum-alloy steels but we would refer to the papers by Dr. George W. Sargent,⁴ J. D. Cutter⁵ and Charles McKnight, Jr.,⁶ the booklet entitled "Molybdenum Commercial Steels" by the Climax Molybdenum Co. and the booklet of the Crucible Steel Co. of America entitled "Almo Steels." While much of this material is propaganda, it is based on experiments made in our own laboratories and plants, in those of the Carbon Steel Co., United Alloy Steel Co. and by Messrs. Wills and Chandler, formerly with the Ford Motor Co. The paper by Dr. Sargent refers to the work of Guillet, Saladin, Swinden and Giolitti in reference to prior use and manufacture of chrome-molybdenum steels of somewhat similar types to those in which interest is now centered. Mr. Cutter's paper proposes the use of a merit index for the comparison of different steels, and makes use of a formula in which the elastic limit, ultimate strength, elongation and reduction are all taken into consideration. A similar suggestion appears in the booklet "Almo Steels," in which the formula is limited to the tensile elastic limit and reduction of area.

In the mills, molybdenum steel has been found to work satisfactorily, being relatively as free from seams and similar defects as the older types of alloy steels; it is also freer from thick and tenacious scale than are the nickel and chrome-nickel types. It seems to flow readily, particularly in drop forgings, and can be worked over quite a wide range of temperature, say, from 2,100 to 2,500 deg. F. (1,150 to 1,370 deg. C.), though the higher temperature would not be recommended for steel above 0.25 to 0.30 per cent carbon.

The steel seems to have a wide safe heat-treatment range, as measured by static tests. But it is not advisable to stress this point as it leads to carelessness in heat treatment. In addition, it has been found that static tests are somewhat misleading in this regard. While many steels of high quality can be forged or heat treated through a considerable range of temperature without apparent loss in static qualities, dynamic or shock tests seem to indicate that for every steel there is a temperature at which the maximum of static and dynamic qualities are obtained. Shock-test methods in this regard are of especial value in supplementing our knowledge of materials or even in detecting faulty heat treatments that static tests do not show. Molybdenum steels seem to machine more readily at a given Brinell hardness than do other steels. This would mean, of course, that parts that must be heat treated and machined afterward could be utilized in a state showing higher physical properties than have been customarily obtainable. The physical property on which molybdenum seems to exert most effect is the reduction of area, which is considered a good measure of toughness.

INFLUENCE OF MOLYBDENUM IN ALLOY STEELS

Molybdenum, particularly in conjunction with chromium, seems to confer the property of deep hardening. This is to be expected from the observation that molybdenum steels resist the drawing temperature to quite an unusual degree. In other words, they require a higher drawing temperature to reduce the physical properties by the same amount that they would be reduced in similar steels without the presence of molybdenum. This indicates that molybdenum tends to keep the carbon in steel in the combined or martensitic form, and when in that condition to retard its passage to the sorbitic or troostitic state. Some years ago the writer sent to Prof. H. C. H. Carpenter,⁷ then at the National Physical Laboratory of Great Britain, a chrome-molybdenum steel together with a variety of commercial high-speed steels for use in his investigations upon the drawing or softening of hardened high-speed steels. This particular steel contained but 4 per cent of molybdenum, 3 per cent of chromium, and about 0.47 per cent carbon, yet it resisted the draw-back temperature, as measured by Prof. Carpenter's etching method, to a greater extent than any of the commercial tungsten high-speed steels used by him, whether of American or British manufacture.

It is possibly too early to make predictions, but the writer believes that molybdenum has established for itself a permanent place among the alloy steels found useful to the airplane, automobile and general engineering trades. It will not wholly displace any other type of steel, but the effect of improvements of this kind and new products has been rather to extend the field of usefulness than to eliminate products of previously demonstrated merit. The bessemer and open-hearth processes, and the electric furnace have not displaced the original crucible cast steel business. The demand for steels made by each method has arisen with the process itself.

Not only does molybdenum below 1 per cent give no trouble from volatilization, but it may be recovered from scrap when remelted in the open-hearth furnace to a large extent.

Legal Notes

BY FREDERIC DANNERETH, PH.D.*

Legal and Official Chemistry

In modern chemical organizations considerable attention is being given to the centralization of the work pertaining to legal and official chemistry. This makes it possible for the executives of a corporation to obtain information quickly when a problem arises. In order to accomplish this purpose it is desirable to have on hand all the literature of importance which pertains to this phase of laboratory work. This includes the *Patent Office Gazette*, the *Treasury Decisions* (of the U. S. Custom House), the *Quarterly* of the National Fire Protection Association, the *Reports* issued by the State Boards of Health, *Transactions* of the Safety Institute of America and the *Rulings* of the Interstate Commerce Commission regarding transport of hazardous chemicals.

The data which are accumulated should be grouped, arranged by subjects and indexed so that they can be brought to the notice of department managers soon after they appear in print. Special attention should be given to patent infringement suits, and court decisions concerning them should, if of local interest, be brought to the attention of each department manager.

If the corporation is about to enter suit, or if it has been sued, it is important that all possible facts relating to the case be collected, so that they may be critically examined. The testimony of the chemist should be carefully prepared so that it may be skillfully presented. Among the commonest forms of law suits are those which arise from breach of contract. Before preparing testimony, the chemist should study all the processes through which a product has passed before it was sold and found to be defective. If for example a vendor has contracted to deliver "best quality rubber jar rings" to a food-canning company, but actually delivers a low-grade jar ring, all the food conserved in jars with the defective jar rings may spoil soon after it leaves the food factory. Here is a case with many possible complications.

CUSTOM HOUSE PRACTICE

In cases where imported products compete with the products of his own corporation, the legal chemist should study the methods used for classifying this imported merchandise according to the U. S. tariff act now in force. He must keep in mind that the meaning of words used in the tariff act is interpreted by the federal courts, and not by expert witnesses. An expert witness may, however, testify to the meaning of words, "as they are used in the trade." He should study the meaning of such terms as unmanufactured article, unenumerated, specific duty, ad valorem duty, similitude, component part of chief value and "products not otherwise specified." He will in the course of his studies find that the person who levies duties on merchandise imported at New York City is officially known as the Collector of Customs of the Port of New York. If the

duty levied is unsatisfactory to the importer, he may "protest" and appeal to the U. S. Board of General Appraisers for a consideration of his case.

CUSTOM HOUSE CASES

Pontianak or Jelutong. The protest of L. L. Littlejohn & Co. against the assessment of duty by the Collector of Customs was filed in 1917. This material had been assessed for duty as an unenumerated, unmanufactured article, but the importer claimed that it was known in the trade as rubber and therefore should be admitted duty free under the tariff act of 1913. The protest was heard before the U. S. Board of General Appraisers, and it was shown to the U. S. Assistant Attorney-General that pontianak is not rubber and is not known in the industry as rubber. However, owing to the stress of the war period, the Government did not push the case and the material was finally admitted duty free. (*Treasury Decisions* 37,284 of July 26, 1917, and *Treasury Decisions Abstract* 41,775 of Jan. 31, 1918.)

Balata Belting. In the case of Robins vs. United States, before the U. S. Court of Customs Appeals, it was decided Feb. 1, 1911, that balata is india rubber by similitude.

Reclaimed Rubber. In the case of United States vs. Michelin Tire Co., before the U. S. Court of Customs Appeals, it was decided, April 24, 1911, that reclaimed rubber is not a manufactured article.

OCCUPATIONAL DISEASES

The investigation of health hazards has been taken up by many of the states through their Boards of Health and is intimately related to the workmen's compensation laws. The duty of the chemist in charge of legal work is then to investigate the special health hazards present in the factory. These may be due to:

1. Overheated rooms.
2. Bad ventilation in rooms where volatile solvents are used.
3. Absence of suction drafts in rooms where powdered minerals are used.
4. Defective ventilation in rooms where poisonous liquids or gases are handled.
5. Bad water drainage in rooms where large quantities of water are constantly spilled out on the floor.
6. Defective flues in rooms where corrosive acid vapors are used for etching, plating or vulcanizing.
7. Absence of suction drafts in connection with lathes or buffing wheels, where fine powders or dusts are formed.

The bulletins on industrial accidents and hygiene published by the U. S. Department of Labor contain a great deal of valuable information on this subject.

FIRE HAZARDS

The legal chemist should collect and file data on fire hazards in factories due to improper storage or use of combustible gases, liquids or solids. For example: In one case it was found that a barrel of chlorate of potash had been stored in a dyehouse, without any label indicating its contents and without any danger signals. When a workman attempted to open the barrel with a hammer and chisel, the chlorate exploded, doing considerable damage to the plant. In another case ground waste rubber was stored in a wooden barrel while still warm from the grinders. Six hours later the material suddenly burst into flame. In the process of coating fabrics with rubber cements a special fire hazard is presented, as large volumes of gasoline are evaporated in a short

Copyright, 1921, by Frederic Dannereth.

*In presenting this paper the author feels that he has given only an outline of the possibilities in this field. Although he has used this plan in his own work for some time, he feels that the idea of grouping all these subjects in one section under the supervision of a special chemist is relatively new.

space of time. The spreading machines must therefore have careful supervision, and steam jets must be stationed so that they can be put in action quickly.

TRANSPORTATION HAZARDS

In the section for legal and official chemistry there should be on file information concerning the risks to which merchandise is exposed while in transit. This may be due to improper loading of freight or express cars; to negligence on the part of employees; to the elements, such as hot weather, cold weather, rain or ocean water. In one case it was found that kitchen ranges made of iron had been placed in a freight car directly next to a barrel of bleaching powder (chloride of lime). The chlorine which emanated from the barrel of bleach during a period of rain attacked the iron and detracted from the value of the stoves. In such cases the "common carrier" may contend that the shipper should mark his package with danger tags, but on the other hand it must be considered that the bleaching powder and not the stove was the real offender. In such instances a careful judge might hold that the "carrier," which in this case was the railway company, must inquire into the contents of all sealed packages delivered to him. This would enable him actually to sort out packages which may cause fire or other damage while in transit.

In one case a cargo of goat skins from the Levant was damaged on shipboard because the hatch had not been closed during a severe storm. As a result of this the salt sea water washed in over the skins, and in that way their value was impaired.

ACCIDENTAL POISONING

In many factories which use chemicals in their processes there are some chemicals which lie around unprotected because they are so commonly used. This in some cases has led to accidental poisoning because of the similarity in name of two substances, one of which was harmless and the other harmful. For example: In one case a workman in a dyehouse was preparing a refreshing drink for a hot summer day. He wanted to mix in some cream of tartar, but accidentally used "tartar emetic," which is a distinct poison. In such cases error should be guarded against by carefully branding all chemicals which are in the class of poisons. Workmen should likewise be cautioned against the careless use of such chemicals as sugar of lead, bichromate of potash and aniline oil. These chemicals are so often exposed in large quantities that the workmen become careless in handling them if not cautioned.

AIR AND STREAM POLLUTION

Most of the industrial states now have enacted statutes governing the pollution of streams with factory wastes. It is therefore desirable to have on file all the recent state laws relating to this subject, as they may affect the dumping of factory effluents into the stream near the factory. In the State of New Jersey it was found about ten years ago that the Passaic River was gradually being converted into an open sewer by the factories situated on its banks. To prevent this from becoming worse, an arrangement was finally made whereby a certain percentage of effluents will ultimately pass out into the open sea through a concrete sewer 20 ft. in diameter.

As an example of air pollution it may be of interest to cite the case of a plant making sulphuric acid in

rotary burners. This plant purchased power from a public utilities company, and one afternoon the power was suddenly shut off, due to a storm. This interfered with the process of manufacture in the sulphuric acid plant in such a way that dense fumes of sulphur dioxide suddenly swept over the surrounding district, killing all vegetation. In this case the pollution of the air was not continuous and was not due to any fault in the management of the plant. However, in the case of the smoke nuisance in large cities containing many steel mills, air pollution may become a permanent health hazard, because it is continuous.

A rather interesting case which grew out of the pollution of a stream is related by Thomas Hancock in his personal narrative published in 1857. When coal gas was introduced in England for the purpose of lighting apartments as well as the streets of towns and cities, the manufacturers of the article found that the tar and other liquid products resulting from the process accumulated upon their hands. By 1800 this had already attracted public attention because the gas companies had begun to dump this "unpleasant and undesirable byproduct" into the rivers. In 1819 Charles Macintosh of Manchester was looking for ammonia to use in the manufacture of cudbear. With this in mind he entered into a contract with the Glasgow Gas Works to receive, for a term of years, the tar and ammoniacal water produced at its works.

In 1823 he had progressed so far with his investigation of the material that he obtained coal-tar naphtha as a distillation product and pitch as a retort residue. He then took out a British patent for preparing a waterproof varnish for cloth, in which he dissolved the pitch in the naphtha and used this to coat the fabric. He also dissolved rubber in the naphtha for similar purposes. The earliest attempts at waterproofing fabrics were in fact made with the use of coal tar and later coal-tar pitch, because many persons at that time were trying to find a use for this product. In the final analysis it was the pollution of the streams which caused these investigators to begin their experiments.

CONTRACT WORDING

The chemist in charge of the work in legal and official chemistry should render assistance to the purchasing agent whenever possible. In the case of contracts and specifications for the purchase of chemicals, the wording used should be such that misunderstandings at a later date will be avoided. This is why many corporations usually append to the contract a specification showing the chemical and physical tests which the delivery must meet. Such items as the shape, composition, size and weight of containers should be noted. Attention must also be given to such general laboratory specifications as color; boiling point in the case of volatile solvents; fineness in the case of mineral powders; and moisture content in the case of textile fibers, rubber and other materials containing large and variable amounts of water.

PATENTS

In order to be of most value a patent should be basic and fundamental. According to section 4,886 of the Revised Statutes of the U. S. it must possess novelty and usefulness. It must not cover, (1) a principle; (2) a property of matter or (3) a result. For this reason it will be well to study the style used in drawing up patents which have stood the test of the courts. It will be found that patents are issued for such things as

chemical processes, chemical products or a composition of matter, machinery used in chemical processes, and the application of a product in the arts to produce new and useful effects. It is important that the student of legal chemistry know the meaning of such terms as priority, interference, validity, abandonment, anticipation, infringement, shop rights and invalid. He should also know what steps are necessary to establish priority for any invention which he or his colleagues may make.

Charles Goodyear discovered that *soft* vulcanized rubber products could be obtained by mixing 6 to 20 per cent of sulphur with crude rubber, whereas Nelson Goodyear, the younger brother of Charles, discovered that if the sulphur be increased 25 per cent or more, he could produce *hard* rubber products. Both inventors were granted patents in the United States for their inventions. Here is an instance where the first inventor did not realize the full possibilities of his discovery.

SPECIAL CASES IN THE RUBBER INDUSTRY

U. S. patent 3,633 was issued to Charles Goodyear of New Haven, Conn., June 15, 1844, for "improvements in the manufacture of india rubber." This patent was contested in the case of Goodyear vs. Providence Rubber Co. It resulted in a decision for the plaintiff, but the defendant appealed and the case was finally decided in the U. S. Supreme Court in 1870. (See Brodix on "Patent Cases," 1869 to 1872, p. 150; and 2 Clifford, p. 35.) Other patents granted to Charles Goodyear in the same year were Nos. 3,461 and 3,462.

U. S. patent 16 was issued to E. N. Chaffee in 1836, for "improvements in preparing and applying india rubber to cloth." Goodyear obtained the rights to this patent in 1844. The patent was, however, contested in the suit of Day vs. Union India Rubber Co., decided by the U. S. Supreme Court in 1857. A U. S. patent was granted on June 7, 1845, to Day, Tyre and Helm for a "machine for cutting india rubber threads." U. S. patent 9,319 was issued to Charles Goodyear, Oct. 12, 1852, for a "method of making india rubber cloth." U. S. patent 4,047 was issued May 13, 1845, to Nelson Goodyear of Newtown, Conn., for the "manufacture of india rubber fabrics."

A U. S. patent was granted on Jan. 11, 1859, to Henry W. Joslin for "improvements in the treatment of india rubber." This process consisted in mixing rubber with zinc sulphide in place of sulphur. In the case of Charles Goodyear and the New England Car Spring Co. vs. Hiram P. Dunbar and Henry W. Joslin, Goodyear asked for an injunction against Joslin. The case was heard in the U. S. Circuit Court, District of New Jersey, in March, 1859, no injunction being granted.

Thomas Hancock on March 18, 1846, was granted a patent in England for an invention covering the use of sulphur to vulcanize rubber, but his original patent is dated Nov. 21, 1843, and this describes how to change the character of caoutchouc by treating it with sulphur and heat. Hancock was a partner of Charles Macintosh, a maker of waterproof cloths in Manchester, England.

Alexander Parkes of Birmingham, England, on March 25, 1846, was granted a British patent for vulcanizing rubber by means of sulphur chloride. He suggested the use of a solution of sulphur chloride in carbon disulphide of about 1.0 per cent concentration.

THE TIRE PATENTS

U. S. patent 554,675 was issued to Arthur Grant Feb. 18, 1896, for "a solid rubber tire for horse-drawn

vehicles." After much litigation the patent was declared valid by the U. S. Supreme Court, April 10, 1911. This patent was also involved in the suit of the Kelly-Springfield Tire Co. vs. Diamond Rubber Co. A decision was rendered in this case by the U. S. Circuit Court of Appeals in New York City, March, 1916. In its decision, the court awarded the plaintiffs 5c. per lb. on the total number of pounds of tires made under the infringement by the defendant rubber company.

U. S. Patent 822,561 was issued to Peter D. Thropp of Trenton, N. J., June 5, 1906, for a "method for vulcanizing rubber tires in a mold, using open steam." This is the one-cure process. The patent was contested in John E. Thropp Sons Co. vs. U. S. Tire Co. A decision rendered by the U. S. District Court, Southern District, New York, in 1915, declared the patent invalid. (226 Federal, 941.)

U. S. Patent 578,551 was issued to E. C. Duryea in 1897 for "an improvement in vehicle tires." The validity of this was contested in the case Buffalo Specialty Co. vs. Indiana Rubber & Insulated Wire Co. in the U. S. Circuit Court of Appeals, Seventh District. (334 Fed. Rep., 334.)

THE RECLAIMED RUBBER PATENTS

U. S. patent 635,141 was issued to Arthur H. Marks of Akron, Ohio, Oct. 17, 1899. The validity of this was contested in the case of Philadelphia Rubber Works Co. vs. Portage Rubber Co. In the U. S. District Court, Northern District, Ohio, April 8, 1915, Judge Charles Clarke presiding, the patent was declared invalid. Another case was that of Philadelphia Rubber Works Co. vs. U. S. Rubber Reclaiming Co. in the U. S. District Court, Western District, New York, June 29, 1915, in which Judge Hazel declared the patent valid. This case was appealed to U. S. Circuit Court of Appeals, Second Circuit, and on Nov. 9, 1915, the patent was declared by Judge Lacombe to be valid. (See Fed. Rep., 225, p. 789; 227, p. 623; 229, p. 150.)

U. S. patent 395,987 was issued to J. K. Mitchell of Philadelphia, Jan. 8, 1889. This patent refers to the reclaiming of rubber from manufactured rubber goods by treating the ground waste with mineral acid under pressure. The textile fibers and a certain part of the mineral matter are thus destroyed or dissolved. In the Marks patent the sulphur is removed from the scrap rubber by treatment with caustic soda under pressure.

U. S. patent 12,983, issued to Beers in 1855, also refers to a process of reclaiming.

THE RUBBER SPONGE PATENT

U. S. patent 1,045,234 was issued to G. Willis and B. Felix on Nov. 26, 1912, for a process of making artificial sponges. In the appealed case of Featheredge Rubber Co. vs. Miller Rubber Co., heard in the U. S. Circuit Court of Appeals, Sixth Circuit, a decision of June 30, 1919, declared the patent invalid, and the case was given to the defendants. The case rested upon the distinction between sponge rubber and rubber sponge. In commenting on this suit the judge remarked: "In some patents we find that the real discovery is not disclosed in the patent specifications, the purpose being to get the protection of a patent and at the same time hold back the knowledge which would allow the public to manufacture successfully at the end of the patent term." (See 250 Fed., 255, and 259 Fed., 565.)

Rubber Trade Laboratory,
Newark, N. J.

Electric Heating in Ceramics

BY WIRT S. SCOTT

Industrial electric heating, which began with the melting of iron in electric furnaces, has proved so successful that its application has spread rapidly. Almost every industry that uses heat is a logical plant for electrical heating, and the glass industry is therefore affected. In fact, many installations have already been made for the treating of glassware.

A 72-kw. furnace is used for annealing glassware, at a temperature of 1,200 deg. F. This furnace is 22 in. wide, 10 ft. long and 5 ft. high, of the overhead conveyor type.

In one test, several thousand goblets were annealed, the goblets being placed in metal containers consisting of nine trays, each tray holding twenty-five goblets, five per row and five rows deep.

RESULTS OF THE TEST

Sixty-five goblets were selected at random during the test, care being taken to select them from different parts of the furnace and were tested in a spectrometer. Sixty-four showed absolutely no refraction of light rays and were passed as A1 grade. One goblet had almost imperceptible refraction of light rays and was therefore rated in this test as B1. The physicist making the test stated that compared with their general run of product this one goblet would ordinarily have been A1 grade. In their natural-gas-fired annealing ovens they have very few strictly A1 grade, a majority being B1 grade, but a quantity also of C1, the lowest possible grade.

All glasses passing through the furnace were bright polish finish. Glasses through the natural-gas furnace have a slight blue finish. Manufactured gas presents a deposit greater than natural gas. Fuel oil deposits a decided white powder finish necessitating washing and polishing, and is therefore prohibitive.

FUSING BIFOCAL OPTICAL LENSES

The work of fusing bifocal optical lenses must be done at a very critical temperature, besides requiring a uniform temperature to prevent resulting strains and a clean atmosphere to prevent spoiling the polished faces of the lenses that are being fused. The lenses are placed on small plaques, four per plaque, and each plaque is covered with a vitreous enameled steel square cup, and fed automatically through the furnace chamber and discharged into an annealing oven. The furnace chamber is in four sections, two sections 18 in. long, each maintained at a different temperature. The annealing oven is 60 ft. long.

When the work was carried on originally through gas-fired furnaces the loss was approximately 20 per cent, whereas the average loss is 3 to 4 per cent when electrically treated.

VITREOUS ENAMELED KITCHEN WARE

Tests were made to determine the practicability of using an electric furnace for vitreous enameled kitchen ware. Thirty-six miscellaneous pieces were fired in the furnace, and a most careful inspection showed that the results were perfect as to polish, absence of pitting, and general smoothness. Due to the ease with which a definite temperature could be maintained it was a very easy matter to get results of the highest order with almost no attention.

Westinghouse Electric & Manufacturing Co.

Belgian Experiments on Palm Oil As Motor Fuel

A series of experiments begun in 1914, but interrupted by the war, has recently been resumed in Brussels on the use of palm oil in internal-combustion motors, announces Trade Commissioner Cross. The question of motor fuel in the Belgian Kongo is a serious one, since a ton of crude oil delivered at Kinshasa in metal casks has an estimated price of 2,000 fr., as against 1,050 fr. in Brussels. Palm oil, on the other hand, costs on the native market an average of 25 centimes per kilo, but varies in price between 8 and 40 centimes. The calorific power of palm oil is from 20 to 25 per cent less than that of crude oil, so that a relatively large consumption of palm oil must be reckoned with, while the comparatively high temperature at which palm oil fuses (37 deg. C.) indicates the possibility of rapidly clogging the motor.

COMPLETE COMBUSTION NECESSARY TO THE UTILIZATION OF PALM OIL

According to engineers closely connected with the experiments, without constructing a special palm-oil motor it was necessary to find a machine in which complete combustion is assured by a complete vaporization of the fuel, which should be introduced in a quantity strictly proportionate to the load. It was further essential that the gaseous mixture should be constant and capable of regulation by a supply of water, varying according to the load and the amount of oil being fed in. Thorough clearing of the exhaust gases was also a requisite.

TESTS PROVED SATISFACTORY

The Belgian colonial company Omnium Africain has been successful in finding a two-cycle semi-Diesel motor of Swedish manufacture developing 10 hp. at 500 r.p.m. which satisfies these conditions, and motors of larger and smaller sizes of the same character have been run on palm oil with good results without special changes for the use of the new fuel. The palm oil, which at normal winter temperature in Belgium has about the consistency of soft butter or lard, is placed in a tank divided into three compartments by wire screening. As this tank is heated either through the circulation of hot water from the cooling system or other mechanical means, the palm oil liquefies and passes through the screening to the feed pipe leading to the injection pump. For experimental purposes this motor is started on crude oil. Once it has warmed up, and as soon as the palm oil begins to liquefy, the crude oil is turned off, so that the engine then runs on palm oil exclusively with no slackening of the number of revolutions or of the power produced. At the temperatures prevailing in the Kongo, engineers claim that this motor could be immediately started on palm oil, and it is proposed to install motors of this type on launches and other small river craft, as well as to conduct further experiments for their use in industry and traction. Analysis shows that there are no incombustible components in palm oil, and, contrary to general expectation, the oil neither clogs the motor nor leaves any perceptible solid residue behind it.

WILL SIMPLIFY FUEL PROBLEM

In case further development of this fuel proves practicable, it will simplify the fuel problems not only of the Belgian Kongo but also of other colonial domains remote from mineral fuel, and where the use of wood only entails much extra labor and other difficulties con-

ected with the various heating capacities of the woods used, to say nothing of the risk of indiscriminate deforestation. The French Ministry of Colonies has conducted experiments with peanut oil, and in July, 1920, the Belgian Ministry of Colonies announced a competition of tractors run on vegetable oils produced in the Kongo, but only one contestant put in an appearance.

The Elaeis palm, from the pulp of the fruits of which this oil is extracted, grows in Africa from Senegal to Angola in a north and south direction, and east to the great lakes. The oil of this tree has been heretofore exported from the Gold Coast, Sierra Leone, Nigeria, Guinea, the Ivory Coast, Dahomey, Togoland, Cameroon, Angola and the Belgian Kongo.

COMPOSITION OF THE OIL

According to analyses by Belgian chemists, palm oil is a mixture of palmitate and oleate of glycerine, with some variable quantities of palmitic and oleic acid. It contains about 95 per cent of fatty acids and appears as a pasty substance of yellowish or salmon color. Its calorific power is estimated at 9,228 calories (Berthelot-fahler), and it is flammable at 210 deg. C. It thus possesses the advantages of being widely grown and easily obtainable, of large calorific power in small volume, of safety in handling and of having no damaging effect on machinery in which it is used.

Synopsis of Recent Chemical & Metallurgical Literature

Manufacture of Linseed Oil.—An excellent illustrated review of the modern technology of linseed oil manufacture as published in the Jan. 5, 1921, issue of *Paint, Oil and Chemical Review* by permission of the William O. Goodrich Co., Milwaukee. The raw material is flaxseed or linseed, the seed of the flax plant. When fibers for use in the manufacture of linen are desired, the flax must be harvested before the seeds are ripe enough to yield a good grade of oil. Thus raising flax for linen and for oil are separate undertakings. Argentina, the United States, India, Russia and Canada are the leading flaxseed producers in the order given. Their combined output has fallen from a maximum of 150,000,000 bu. in 1912 to an average to 50,000,000 bu. for the last four years.

Linseed contains from 33 to 40 per cent of oil, but the actual yield of oil varies from 26 to 35 per cent. The oil may be obtained by three processes: Hot-pressing, cold-pressing and extraction with volatile solvents. The first of these—known as the "old process"—is used almost exclusively in this country. After cleaning, the linseed is pressed through 5-high chilled crushing rolls the function of which is not to express the oil but simply to break down the structure of the kernel to a flaky condition. This assures a stratified cake with a minimum resistance to the flow of oil in the press. The ground seed is carried by screw conveyors to jacketed kettles, where it is heated to about 180 deg. F. in order to soften the oil cells and decrease the viscosity of the oil. A hydraulic cake-former molds the meal into proper size and form to fit the press boxes. Sufficient pressure is exerted in the former so that the hydraulic presses can be built of an economical working height without sacrificing capacity. In order to hold the cakes in the press and prevent them from squeezing out, firecloth is wrapped around the meal. Pressure control in the presses is automatic and after about an hour the cakes are removed to automatic trimming machines, where the dry edges are removed and returned to the process. The

cleaned cakes are sold for cattle feed or fertilizer. The raw oil is settled to remove foots, filtered, and is then ready for sale as such or it may be converted into boiled or refined oil. As a rule, boiled oil is made at present from raw oil by the addition of red lead and manganese driers, by expelling the moisture and by bodying the oil to the desired gravity. The refined oils are many in number to meet the exacting requirements of the trade.

While the paint grinder is still the largest consumer of raw linseed oil, there is a constantly growing demand from makers of foundry core oils, putty and linseed oil soaps. Boiled oil is used largely as a ready-mixed paint vehicle, though lesser quantities are consumed in the manufacture of window-shade cloth and similar fabrics.

The refined oils may be classified according to use as grinding oils, varnish oils, and oils of the blown or oxidized type. Refined linseed oil in some form or other is used chiefly in the manufacture of paints, varnishes, enamels, linoleum and oilcloth, patent leather, oiled clothing, imitation leathers and printing inks. It has no value as an edible oil, an illuminant or a lubricant. A discussion of the use of metal containers instead of cooperage, an outline of methods of analysis and a glossary of technical terms conclude the article.

Note:—The following data, compiled recently by the Tariff Commission, form a logical supplement to the above review of the industry:

Domestic production of flaxseed for 1912-1916 averaged 15,000,000 bu. of 56 lb. North Dakota, Minnesota, Montana and South Dakota produce the bulk. Imports in 1918 were 12,785,034 bu. valued at \$33,830,735. Exports are relatively insignificant, 21,481 bu. in 1918, mostly going to the United Kingdom and Canada. In 1919, domestic production of linseed oil amounted to 224,627 tons (59,900,000 gal.) obtained from 678,903 tons of flaxseed. Imports since 1912 have been less than 0.3 per cent of the production in this country. Since 1914 the exports of linseed oil have been about 1,200,000 gal. per year.

Selenium Chloride.—In the January number of the *Journal of the American Chemical Society* (vol. 43, p. 29) there is a very interesting note on selenium oxychloride by Victor Lenher. It may be recalled that when Dr. W. R. Whitney received the Perkin Medal this year he said in his address on "The Biggest Things in Chemistry," "and so I note such researches as Prof. Lenher's on selenium oxychloride, and I say to myself, 'Watch it grow!'"

The present paper contains a great deal of information of which we repeat some of the high lights. It is slightly yellow, transparent to visual light, but so opaque to ultraviolet that it makes practically a screen for all wave lengths below 4,050. It is miscible in all proportions with carbon tetrachloride, chloroform, carbon disulphide and benzene. With saturated aliphatic hydrocarbons at ordinary temperatures there is apparently no chemical reaction, or if there is any it is very slight. The unsaturated hydrocarbons of the same series, on the other hand, unite with selenium oxychloride directly, frequently with the manifestation of great energy. Amylene, for instance, reacts with it with great violence, and with such hydrocarbons as turpentine the reaction is like that of halogens on turpentine. It is thus possible to separate such unsaturated aliphatic hydrocarbons as amylene from the saturated heptane by simple contact with this solvent. Again, if a mixture of heptane and benzene is treated with it, the benzene goes into solution, while the lighter heptane rises to the top and forms an immiscible layer.

Sulphur, tellurium and selenium dissolve with ease in the cold liquid; most metals react with it, forming the chloride of the metal and red-brown selenium chloride. It dissolves many metallic oxides, and solutions of molybdenum trioxide and the pink carbonate of cobalt show remarkable photochemical reactions. With carbonates its reactions are of considerable variety. Barium sulphate is peptized by it to a gel much resembling freshly precipitated aluminum hydroxide, but the colloidal form of barium sulphate is immediately changed back to the ordinary form when treated with water.

Protein materials, such as hair, bristles, silk and leather, are readily dissolved in the cold. Vegetable and fish oils

behave in a way similar to treatment with sulphur monochloride. With linseed oil it forms a rubber-like mass similar to that produced by sulphur monochloride. Menhaden oil reacts with selenium oxychloride also to form a waterproof rubber-like mass. Rubber reacts chemically with it, and the chemical character is changed in the process. Phenolic condensation products, gums, resins, dried paints, shellac, dried varnish, agar, celluloid, gelatine, glue—including the insoluble casein glue—are all readily dissolved by it in the cold.

Natural asphalts, resins and bitumens dissolve with ease in the cold when they are of unsaturated character. Such a product as ozokerite, which consists principally of saturated hydrocarbons, behaves very like paraffine with it. Natural coals brought into contact with selenium oxychloride react so far as the bituminous and resinic materials are concerned, leaving a carbonaceous residue behind. Thoroughly ignited coke loses nothing with the reagent, whereas incompletely coked soft coal goes partially into solution. Anthracite coal shows little reaction, semi-anthracite loses considerable, and bituminous coals lose a great deal. Lampblack loses its hydrocarbon content, leaving behind carbon.

The carbonaceous material separated from iron and steel by the copper chloride treatment consists of graphite and what is believed to be unsaturated hydrocarbons. With selenium oxychloride a black extract is produced which shows that at least a part of the material has been acted on. Further study of this with a view to throwing light on the constitution of iron and steel is advised by Prof. Lenher. It is truly a remarkable solvent.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Ammonium Sulphate.—In the "semi-direct" method of recovering ammonia as sulphate from coke-oven gases the hot vapors from the ammonia still are further heated by means of the waste gases from the coke ovens and then mixed with the cooled gases from the tar extractors, the mixture then passing to the saturator; the heat thus supplied prevents dilution of the acid in the saturator by the water present in the gases. Using the apparatus shown, the gases from the ovens 1 pass through coolers 3, a tar

condenser 4 and a tar extractor 7 to the saturator 8; the ammoniacal liquor and tar from the coolers 3 and condenser 4 flow to a tank 5, whence the ammoniacal liquor passes to a tank 6, from which it is pumped to a still 10; the vapors from the still pass through a heater 11, in which they are heated to about 200 deg. C. by the waste heating gases from the ovens, and the heated vapors pass by pipe 12 to mix with the cooled gas on its way to the saturator. (Br. Pat. 153,177; SOC. FRANCO-BELGE DE FOIRS A COKE, Brussels. Jan. 12, 1921.)

Separation of Alkaloids.—Alkaloids are selectively isolated from drugs containing more than one constituent by taking advantage of their varying basicities and their

different solubilities in various solvents. The raw alkaloidal material containing more than one constituent, mixed if necessary with powdered vegetable tissue, is acidified and treated with a suitable solvent, whereby the weakly basic alkaloids are extracted, leaving the strongly basic alkaloids fixed in the tissue. Further vegetable tissue is then added to the concentrated extract and the weakly basic alkaloids fixed thereto by the addition of acid. By a choice of solvent, one alkaloid can be extracted from all the remainder. The isolation of morphine from opium and the separation of the remaining alkaloids into weakly and strongly basic components are described in the example. Alkaloids of the narcotine group comprise the weakly basic components. (Br. Pat. 153,219; CHEMISCHE FABRIK VORM. SANDOZ, Basel, Switzerland. Jan. 12, 1921.)

Dinitrophenol.—Phenol is nitrated at 95 deg. C. with dilute nitric acid, which is fitted for further use by addition of strong acid from a nitrogen oxides absorption tower. The phenol is fused in a vessel *K* and nitrated in a vessel *A* fitted with a stirrer, the nitrous gases evolved being absorbed by dilute nitric acid in the tower *T*. The dinitrophenol is then collected on the filter *B* and the spent acid, after

mixture in the tank *C* with strong acid from the tower *T*, is forced to the vessel *E*, which supplies the nitration acid and the absorption acid. The nitric acid content of the system is maintained by introducing fresh nitrous gases by the pipe *F*. (Br. Pat. 153,265; not yet accepted; NORSK HYDRO-ELEKTRISK KVAELSTOFKTIKESKAB, Christiania, Jan. 12, 1921.)

Catalyst for Synthetic Ammonia.—A catalytic material, for use in the synthetic manufacture of ammonia under conditions of super pressure, consists of an oxide of iron, approximating in composition to Fe_3O_4 , prepared by directing a jet of oxygen on to molten iron monoxide. A small quantity of lime may preferably be incorporated in the product. A bar of iron or steel is fused under a jet of oxygen and the molten product, which consists of iron monoxide mixed with iron, is collected in a crucible preferably of magnesia. At this stage 5 to 10 per cent of lime may be added, together with a small amount of alkaline oxides. The jet of oxygen is then directed upon the molten mass, whereby large quantities of heat are evolved, the mass becomes agitated, and the lime is dissolved in the oxidized melt, as well as some of the magnesia of the crucible. The treatment is continued until the mass is completely homogeneous, or if impurities are present, until the surface begins to congeal, when the product is cast on a sheet of iron. Specification 130,086 is referred to. (Br. Pat. 153,254; not yet accepted; SOC. L'AIR LIQUIDE—SOC. ANON. POUR L'ETUDE ET L'EXPLOITATION DES PROCÉDES G. CLAUDE, Paris. Jan. 12, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Tariff Hearings on Chemical and Metallurgical Products

In framing the new tariff bill, the Committee on Ways and Means of the House of Representatives has been asked by representatives of the chemical glassware industry, the chemical porcelain industry, and by representatives of the manufacturers of scientific apparatus to eliminate the duty free clause on such materials which are intended for educational or scientific purposes. It was contended that 50 per cent of the chemical porcelain imported comes in duty free under this paragraph. Since the last hearing on this subject, the opinion of students has been consulted and it is found that a large percentage of them favor paying a slightly higher price for their apparatus so as to encourage an American industry. It was testified that the domestic industry cannot hope to expand if it cannot undertake quantity production. To do that it must have the full market rather than 50 per cent of it, it was stated.

In connection with this item, Dr. Charles H. Herty was asked this question by Representative Garner: "How is it that the German people can pay \$2,000,000,000 a year taxes to a foreign country, pay 12 per cent export duty, and still be able to destroy their competitors throughout the world? What I cannot understand is how some people are so superior to other people that they can come over here and put our commercial people out of business." In his reply Dr. Herty stated that the practice is to sell articles below cost until competitors are destroyed and then advance prices to the very limit, thus recouping losses. In addition, he said, the exchange rate offsets some of the disadvantages against which the Germans must contend.

PHOSPHORUS

A duty of 18 cents a pound on phosphorus has been asked by C. W. Asbury of the American Phosphorus Company. This is the old Payne-Aldrich rate. If it were not for the difficulties of transportation, Mr. Asbury declared, a much higher rate would be necessary to enable an American manufacturer to compete with foreign producers.

The witness introduced a letter from General Fries of the Chemical Warfare Service to the effect that phosphorus is a most essential commodity for the prosecution of war and that the country should be independent of foreign sources of production. Mr. Asbury testified that the plant of his company at Philadelphia is the only one in the United States and that it has been closed since November 1 because of inability to compete with foreign producers. He stated that the annual peace-time consumption of phosphorus in the United States is 1,000,000 pounds. In addition to the use of phosphorus in the making of matches, it is used in quantities in the manufacture of phosphor-bronze bearings and as a substitute for camphor in the manufacture of celluloid articles. Small quantities are used in laboratories and as drugs. The military uses of phosphorus, Mr. Asbury testified, are to create smoke-screens, in the manufacture of range-finding bullets, and in chemical warfare.

FERROMANGANESE

Ferromanganese will be dutiable at two cents a pound if Congress should approve the rate requested by E. G. Lavino and other ferromanganese manufacturers, who appeared before the Committee, and testified that this rate is necessary to protect the domestic industry against the very aggressive competition afforded by English manufacturers. It was stated that the English manufacturers have formed a pool and that it is its deliberate intention to wreck the American ferromanganese manufacturing industry.

These witnesses pointed out, however, that should a duty

be placed upon imports of manganese ore, it would be necessary to increase accordingly the rate of duty asked on ferromanganese. They are not opposed to some degree of protection for the domestic manganese mining industry but it was very apparent that this position was taken simply to avoid the inconsistency of urging protection for their products while at the same time asking that the product of another industry be placed on the free list. Mr. Lavino stated that there is not a sufficient quantity of manganese ore in the United States to permit of any great development of manganese mining while at the same time deposits are of poor quality and at a distance from the points of consumption.

ARSENIC

Arsenious acid and arsenic acid are now on the free list. Congress has been requested to place a duty of five cents per pound on these articles and a proportionate rate on the arsenic content of Paris green and London purple, in the interest of the domestic arsenic industry. An ad valorem duty of 20 per cent is asked for other arsenical compounds. The Committee was also advised that a modern plant for the manufacture of white arsenic just has been completed at Toulon, Nevada.

Continuance of Work at Wilson Dam and Muscle Shoals

During a hearing on the item in the Sundry Civil Bill calling for \$10,000,000 for the continuation of the work on the Wilson dam, the proposed operation of the nitrate plants at Muscle Shoals was discussed at length. One of the important developments was a statement by Colonel Hugh L. Cooper, who is acting in a consulting capacity with the Corps of Engineers, to the effect that it would defeat the power plan if the first 80,000 horsepower of secondary power were used to operate the nitrate plant. In that connection, Colonel Cooper said:

"Such a first use of 80,000 horsepower secondary power would defeat my power plan. The first 80,000 horsepower secondary power will produce 446,000,000 kilowatt hours for an average period of slightly over 10 months per year. Compare this first 80,000 horsepower with the last 80,000 horsepower of secondary power. The last 80,000 horsepower of secondary power will produce an average of only 172,000,000 kilowatt hours for an average period of 4 months per year. Power that is good for 10 months per year is worth at least 33½ per cent more per kilowatt hour than the same kilowatt hour power that is good for 4 months per year. I feel quite certain that the taking away from the secondary earning capacity in my plan now before you of the first 446,000,000 kilowatt hours per annum would be taking off so much of the cream of this business as to make the remaining skim milk not worth building transmission lines for. Transmission lines cost practically the same whether used 4 months or 12 months of the time per year."

Colonel Cooper stated that the development can be made a paying one, provided it is confined to power. In addition to saving \$9,500,000 a year to the consumers of power within a radius of 250 miles of Muscle Shoals, he has submitted figures showing that the government can make 5 per cent on its investment after the project is complete and ultimately get back all of the money invested. In view of the great benefits to be derived from this development, he said it would be a national crime if the work were stopped now and the \$17,000,000 invested thrown away.

Dr. Charles L. Parsons appeared in opposition to the operation by the government of the nitrate plant. He dis-

cussed the various processes used in the fixation of atmospheric nitrogen, declaring among other things that the cyanamide process is in a condition of obsolescence and that he does not expect to see it in operation in any country within a few years. He declared that the question of sludge disposal alone would make it very difficult to operate the cyanamide plant at Muscle Shoals, and that such a scheme as proposed by the War Department never would be able to meet its expenses. He called attention to the fact that it will be necessary to build an ammonium sulphate plant at a cost of at least \$3,000,000.

Patents for Government Employees

Determined opposition has developed in the Senate against that section of the conference report on the Patent Office bill which authorizes the Federal Trade Commission to administer patents for Government employees. As this is written, it seems likely that the Senate conferees will recede from their demand that this section be included in the bill. Senator Reed of Missouri has stated on the floor of the Senate that the bill cannot become a law at this session, unless that section is eliminated.

The House has accepted the conference report including the Government employees section. The Senate is willing that the salaries in the Patent Office be increased and that the force be enlarged as is provided by the main bill. The Government employees section is a rider on that measure, which was attached in the Senate.

Senator Reed based his opposition to the measure on his belief that the bill would give an unfair advantage to a Government inventor as compared with an outsider who might not have a salary to keep him going. He also objected to the licensing feature of the plan. By right, he said, an invention made by a Government employee should belong to the Government, but to stimulate effort he admitted the advisability of allowing a Government employee to take out a patent. His objection to the bill was that it places them on a different footing than other persons.

Senator Norris of Nebraska, who is supporting the conference bill, declared it would be a step toward protecting the poor inventor against infringement of his patents by powerful interests. He said that it is admitted by all that any poor inventor can be worn out in the courts and his patent infringed with impunity. He accused large interests of suppressing thousands of inventions annually so as to prevent competition in their line or make necessary improvements in their plants, to the great detriment of the public.

Investigation of Sulphur and Phosphorus in Steel

An interesting co-operative investigation on the effect of sulphur and phosphorus in steel has already been described in these columns.¹ Thirteen heats of rivet steel having "residual" sulphur varying from low to quite high were made some months ago by the Carnegie Steel Co., and a comprehensive program of physical tests is now being conducted at the Watertown Arsenal.

In co-operation with the Bethlehem Steel Co. a beginning has been made in the manufacture of material to show the effect of additions of sulphur to otherwise first-class steel. Three heats have been manufactured of steel having carbon contents of 0.18 to 0.22 per cent, 0.35 to 0.45 and 0.65 to 0.75 per cent, typifying roughly plate and structural steels, forging steels, and wheel, tire and rail steels. The steel was made by the regular commercial basic open-hearth practice and each lot was a part of a 45-ton heat. The original sulphur content of each heat was 0.04 per cent or below; more sulphur was added in the form of iron sulphide in a pouring box located between the ladle and the ingot mold. For each carbon content it was aimed to have a series of sulphur content ranging from 0.04 to 0.15 per cent. The object was thus the production of ingots of steel identical in composition in all respects except the sulphur content. Ingots, 16x16x57 in. in dimension were rolled to 4x4 in. billets and then portions of them for test

were further rolled to 1 in. rounds, and a portion of the billets rolled also to 1 in. flats, so that material for test can be taken transverse to the direction of rolling. In order to compare the effects of added and residual sulphur it is planned to remelt the discarded portions in two lots, one high in sulphur and one low in sulphur.

An active search is being made for stock material containing abnormal amounts of sulphur and phosphorus which has given good service, or on the other hand, stock material containing normal impurities which has been unsatisfactory. Automobile manufacturers, railroads, and steel foundries are requested to notify the committee (C. L. Warwick, Chairman, 1315 Spruce St., Philadelphia) whether they have material of this sort which would be available for test. So far little or no material of high phosphorus or sulphur content has been obtained, and there seem to be practically no records in the companies interviewed of failures that can be attributed to high phosphorus or sulphur.

Philippine Palm Products

Dr. H. D. Gibbs addressed the South Jersey Section of the American Chemical Society at the regular meeting in Carney's Point, N. J., on Wednesday evening, February 16, 1921. His subject was "The Palm Trees and Their Products." The lecture was illustrated with many interesting views taken by the Bureau of Science during the speaker's service in the Philippine Islands. Although there are about seventy-eight species of the palm tree known, there are only five that are of commercial importance in the Philippines, namely, the coconut, nipa, cabonegro, fish-tail, and buri palms. The date palm requires a dry climate and therefore is not found in the Philippines. The coconut palm yields a wide variety of products ranging from nut-butter to thatched roofs. The nipa palm is an important source of alcohol.

Nipa palms can be tapped every year for an indefinite number of years. The flower stalks are cut off, and the sap flows for two to three months. Buri palms can be tapped but once. They grow to a height of 60 to 80 ft., compared with 15 to 20 ft. for nipa palms. The trunk of a buri palm may be over 2 ft. in diameter, and often contains several tons of starch. The top of the tree is cut off, and due to the action of a diastase the sap that flows out contains practically nothing but sugar. During a period of several months all of the starch in the tree is converted into sucrose. The flow of sap then stops and the tree is dead.

The sap from these palm trees analyzes about 15 per cent sucrose. Immediately after it is exposed to the air it starts to ferment, and within a very few hours all of the sugar is converted to alcohol. This occurs while the sap is being transported to the distilleries. The speaker said that by painting the inside of the sap-collecting vessels with a lime-sulphur preparation, he was able to prevent this fermentation, and thus the sucrose solutions could be preserved for several weeks until they could be transported to a sugar refinery. This opens the possibility of converting the palm alcohol industry into a palm sugar industry and promises a very cheap source of sugar.

International Steel Conference Proposed

At a meeting of the directors of the American Iron and Steel Institute held in New York on Feb. 25, the chief topic of discussion was concerning the international aspects of the steel market. A suggestion has been received from steel producers in England, France and Belgium for the calling of an international steel conference of steel makers of all nations active in the trade. The object of such a conference would be discussion of general economic conditions in the industry as well as an interchange of ideas dealing with economies in manufacturing. The matter was referred to Judge Elbert H. Gary in his capacity as president of the American Iron and Steel Institute. It is expected that the plan for the proposed conference will be studied by officials of the Institute and a report made at the spring meeting.

¹CHEM. & MET. ENG., VOL. 22, PP. 297, 609, 952.

Personal

Dr. RAYMOND F. BACON, director of the Mellon Institute of Industrial Research of the University of Pittsburgh, has returned from Europe, where he spent the holidays in France and Italy in the investigation of nitrogen-fixation processes.

STUART CROASDALE of Denver, Col., announces that he and his associates have opened an Eastern office in the Magee Building, Pittsburgh, Pa., for the purpose of conducting a business in mining and metallurgical engineering. The new organization will operate under the name of Stuart Croasdale & Co., and will maintain a Western office in Denver, Col.

J. V. N. DORR addressed the Cleveland section of the American Chemical Society on Feb. 21 on the subject of "Some Continuous Operations in Chemical Industry."

JUNIUS D. EDWARDS, chief of the physical chemistry division of the research bureau, Aluminum Co. of America, at New Kensington, Pa., has been appointed assistant director of research.

JAMES B. GRAHAM, president of the Northern Central Trust Co. of Williamsport, Pa., has been elected president of the board of managers of the Crescent Refractories Co., Curwensville, Pa.

H. H. HILL has been appointed superintendent of the Bureau of Mines petroleum experiment station at Bartlesville, Okla., succeeding A. W. Ambrose. Mr. Hill was formerly employed as a chemist in the Pittsburgh and Washington laboratories of the bureau and was transferred to Bartlesville about a year ago for work on refining problems.

FRANK HODSON, president of the Electric Furnace Construction Co., Philadelphia, Pa., has been elected a member of the executive committee of the Philadelphia Foundrymen's Association.

N. C. HOYLES has been appointed manager of the Cincinnati branch of the Pittsburgh Testing Laboratory, at 813 Race Street, Cincinnati, Ohio. From 1909 to 1914 Mr. Hoyles was manager of the Birmingham, Ala., branch of this company. In 1914 he joined the Canadian military forces and went overseas with the Canadian engineers. For the past year he has been assistant manager of the Pittsburgh Testing Laboratory's New York office.

W. W. ODELL of Urbana, Ill., has been selected to take immediate charge of the lignite investigation which is being conducted by the Bureau of Mines. The bureau is preparing to conduct experiments on a commercial scale with North Dakota lignite. Mr. Odell, who has been doing coal gas work at the Urbana Station of the Bureau of Mines, has 15 years' experience in this type of work, and has been with the Bureau of Mines since 1917.

Mrs. FREDONIA JOHNSON PRATT of St. Louis, Mo., widow of the late Dr. David S. Pratt, assistant director of the Mellon Institute of Industrial Research of the University of Pittsburgh, has established in that institution an industrial fellowship as a memorial to Dr. Pratt. The incumbent of this industrial fellowship will conduct research in that field of organic chemistry in which Dr. Pratt was especially interested.

EDGAR S. ROSS, who has been doing private research work with Professor C. James, New Hampshire College, Durham, N. H., for the past 18 months, was recently transferred to Philadelphia, and will continue research investigations at the Greenwich Point Laboratories of the Pennsylvania Salt Mfg. Co. Previous to the work at New Hampshire Mr. Ross was engaged as chief chemist and plant supervisor for Charlotte Chemical Laboratories, Inc., and Columbite Reduction Co., both of Charlotte, N. C.

C. W. SUTTON has been re-elected president and general manager of the American Vulcanized Fibre Co., Wilmington, Del., at a recent meeting of the board of directors.

WILLIAM BOYCE THOMPSON received the honorary degree

of doctor of laws at the Charter Day exercises of the University of Pittsburgh, on Feb. 18. On the same occasion the honorary degree of doctor of science was conferred upon C. H. MacDowell, president of the Armour Fertilizer Co. and director of the chemicals division of the War Industries Board during 1918. These honors were given upon the recommendation of the Mellon Institute of Industrial Research.

CARL A. WENDELL, chief engineer of the American Ore Reclamation Co., New York, has been retained by the General Briquetting Co. as consulting engineer in flue dust briquetting, coal washing, and coal briquetting.

CHARLES S. WITHERELL, recently on the metallurgical staff of Guggenheim Brothers, has entered private practice as metallurgical engineer at 150 Nassau Street, New York.

Dr. J. C. WITT has been placed in charge of chemical research for the Portland Cement Association. This work is being carried on at the Structural Materials Research Laboratory in co-operation with Lewis Institute, Chicago. For a number of years, as chemist and chemical engineer, Dr. Witt has been identified in various ways with the manufacture and use of cement and other materials of construction.

Obituary

H. B. ROSENGARTEN, for many years one of the most widely known chemical manufacturers of Philadelphia, died Feb. 20 at his home. He was eighty-four years old. Mr. Rosengarten formerly was head of the Powers-Weightman-Rosengarten Co. of Philadelphia. He retired from active business several years ago.

Book Reviews

THE MANUFACTURE OF SUGAR FROM THE CANE AND BEET. By T. H. P. Heriot, F.I.C., Lecturer on Sugar Technology at the Royal Technical College, Glasgow. New York: Longmans, Green & Co., 1920. x + 426 pp., 39 figs. Price, \$8.50.

Treatises on manufacturing technology usually emphasize either the theoretical or, more commonly, the descriptive side. That this book falls within the former classification may be seen from the opening paragraph of the preface:

It has often been stated that the sugar producer can only be trained in the factory, theoretical knowledge being of little value. The aim of the present work is to show that successful practice is becoming more and more dependent on scientific principles, which can be studied more effectively outside the factory than inside.

In the plan of the book the manufacture of cane and beet sugar is carried along in parallel chapters, the theoretical treatment usually being followed by some description of the important machinery. While this dual arrangement may appeal to some, the reader who is particularly interested in either branch will be apt to find it more annoying and confusing than valuable. It also leads to some difficulties, as we find the filtration of beet juices discussed in chapter XVIII before the chemical treatment is reached in the following chapter. In the reviewer's opinion, the point more deserving of emphasis is that the sugar technologist should acquire familiarity with the technic of other manufacturing industries; for example, it is only recently that certain improved types of filters have been introduced into the sugar industry which have been standard in metallurgical work for a number of years.

The subject of juice extraction from the cane is thoroughly and interestingly handled, and a good theoretical treatment of the diffusion process for extracting sugar from the beet is given. Mention should be made here, however, of the importance of having battery supply water as low as possible in dissolved solids. The chapter on

evaporation is meager and wholly unsatisfactory. No discussion is given of the value of vapor heating, and the Wellner-Jelinek type of evaporator is not even mentioned. On the subject of crystallization the author is plainly more at home and deserves credit for his treatment of this section. The use of the term "first molasses" is unfortunate, as it is general practice, at least outside of the British Isles, to restrict the designation "molasses" to the final, exhausted mother sirup.

The subject of refining is treated in the last section of twenty-six pages. The author has attempted a good deal in trying to cover the three branches of sugar technology in a book of 400 pages. Under these circumstances it is hardly fair to criticize him for concentrating on the important phases and omitting many details of less importance. In some respects, however, the book could be improved by a more comprehensive treatment of some things and by the omission of others, such as some of the antiquated desugarization processes for molasses.

So many technological works are mere descriptions of processes and machinery that a book which deals primarily with the "scientific principles" is a relief and more than welcome. As such it should offer much stimulation both to the student and to the so-called "practical man." Less can be said for the descriptive matter, which is inadequate except in a few cases.

S. J. OSBORN.

MACRAE'S BLUE BOOK, VOL. XI, 1920. 1855 pages.

Chicago: MacRae's Blue Book Co., 1920. Price, \$10.

Chemical and metallurgical engineers will find much to interest them in this unusual directory. Its classified material section serves as a buying guide for the wide variety of materials required by any large industrial organization.

In addition to the alphabetical lists of manufacturers and of trade names which are common to directories of this type there are two special sections which serve to round out the usefulness of the book. The first of these is an indexed collection of miscellaneous data including weights and sizes of sheet lead, lead pipe, copper, brass and steel tubing, cast and wrought iron pipe, pipe fittings, wire, sheets, structural shapes, etc. Finally there is a standard list price section (including differentials and extras) covering a multitude of iron and steel products, belting, glass and other plant supplies. The calculation of discounts is facilitated by the use of a table giving the equivalent discount and net price corresponding to the usual trade discounts. This is supplemented by a five-place logarithm table of numbers from 0 to 999.

ALAN G. WIKOFF.

Current Market Reports

The Chemical and Allied Industrial Market

NEW YORK, Feb. 25, 1921.

The chemical business in general appeared quiet during the past week and spot material was not moved in very large dimensions on account of the accumulated stocks of important material in the warehouses. A fair amount of miscellaneous inquiries, however, have been filled in the open market, but the major portion of these were for small lots for immediate delivery. Underneath the surface of the market, some of the largest manufacturers have been able to place a good volume of business on contract with their regular trade and this condition holds true of several important lines. Offerings of foreign chemicals have not caused much of a dent in domestic quotations, but have created a feeling of uncertainty among large buyers which tended to retard actual consummation of new business.

Factors close to the heart of trade conditions admit that sentiment is somewhat mixed. In some industries a marked improvement is noted, although indications are still for a period of a hand-to-mouth business based to a large extent, upon immediate requirements. It now seems clear that the process of placing business upon a level fairly comparable with that which prevailed prior to the war is in progress.

Precipitate declines in commodity markets seem to be passed. Even with the continued declining tendency normal business at a satisfactory profit is possible.

One of the strongest items in the chemical list was *soda ash*. The relatively small supplies in the hands of dealers and jobbers were fully reflected at intervals and prices were occasionally advanced where buyers needed immediate delivery. Inquiries of carlots from Western consumers kept trading moderately active at well sustained prices which ranged from \$2@2.10 per 100 lb. for carload lots and up to \$2.50 for smaller quantities. On the other hand resale offerings of solid *caustic soda* appeared slightly freer and these had a tendency to depreciate spot prices because the demand did not assume active proportions. At intervals during the week caustic sold as low as \$3.70 and as high as \$3.90 per 100 lb. At the close resale material was quoted at \$3.70@3.80 per 100 lb. with contract prices unchanged at \$3.60 per 100 lb. basis 60 per cent f.o.b. works. Foreign *muriate of potash* was offered at \$67@70 per ton basis 80 per cent f.o.b. N. Y. A good inquiry is reported for this important basic chemical and some business is going through. Buyers, however, are below these figures and it looks as though concessions would have to be granted to insure any active business.

Slightly lower prices were named by prominent dealers of *acetate of soda* and goods could be obtained at 5½c. per lb. f.o.b. works for prompt and future shipments. This price holds good only for round lots, smaller quantities being held as high as 6½c. per lb. Inquiry at present seems to be confined mostly to small lots for actual requirements. Moderate quantities of resale *bicarbonate of soda* are offered by dealers at \$2.50 per 100 lb. in barrels, spot N. Y. Producers still quote the market at 2½c. per lb. in barrels and 3c. in kegs f.o.b. works. Most holders of *bichromate of soda*, resale stock, are quoting the market at 8½c. per lb. Occasional sales of small lots went through at 8½c., but there seems to be no apparent pressure of round lot offerings and it is doubtful if better than the outside figure could be done on carlots. Moderate offerings of outside makes were on the market at concessions, prices depending chiefly on the quantity desired. March shipments were generally quoted at 8½c. per lb.

Amyl acetate, technical, was quoted lower by some prominent sellers, and it was stated that business could be placed at \$3.25 per gal. Quotations were heard at \$3.25@3.50 per gal. depending upon the quantity. Scattered sales of imported *barium peroxide* have been reported of late and in one quarter the sale of a carlot at 17c. per lb. is recorded. The general quotation, however, ranges from 18@22c. per lb. Producers of *formaldehyde* remained steady at 18c. per lb. minimum for round lots and 20c. for smaller quantities. Moderate lots of resale stock are obtainable through second hands at 17½@17¾c. per lb. Some sales were reported at the inside figure. An easier feeling was noted in *prussiate of soda* on spot during the week and there were sellers from 16c. down to 15½c. per lb. Absence of important consuming inquiry has stimulated competition among dealers and prices have been reduced accordingly. Prompt shipments from abroad were obtainable at 15c. per lb. Scarcity in offerings of yellow *prussiate of potash* is keeping this chemical in a firm position and the best price heard was 28c. per lb. for small quantities only. Prompt shipments were quoted at 27c. per lb. The red variety also remained very scarce with sellers quoting 50@55c. per lb.

White *arsenic* on spot is to be had as low as 9c. per lb. in very fair volume. In some quarters prices are named up to 10½c. per lb., but no business has been reported above 10c. Producers' prices on *caustic potash* are lower, but in view of the demoralized state of the market this factor has had no noticeable effect. Resale lots of caustic of standard domestic brands are offered on the spot as low as 10@12c. per lb. with some dealers even in a position to shade the low figure on firm business. Imported caustic potash is offered at 11@13c. per lb. Producers are quoting 16@18c. per lb. admitting they are willing to shade these figures for real business. Producers of *copper sulphate* have reduced their quotations and in some directions stocks are to be had as low as 5½c. per lb. from manufacturers, although others are quoting up to 6c. per lb. The market for imported

material is very uncertain with a nominal quotation given as 5½c. per lb. No large stocks of imported sulphate could be located.

Manufacturers of *sulphuric acid* are holding prices fairly firm, although in the absence of actual business some shading has been done in certain quarters. Slowness throughout the chemical industry is reflected in the light demand for sulphuric. Producers, however, have held prices exceptionally firm considering all these conditions. Their attitude is that requirements will have to be taken care of whatever the price and they are not disposed to set a figure which will not yield them a fair profit. Prices remained quatably unchanged at former levels throughout the entire group.

COAL-TAR PRODUCTS

Interest in the different branches of the coal tar products market reflected improvement. Buyers for both domestic consumption and export are entering the market with orders of larger volume for spot material, but there still lacks keen interest beyond present needs and little talk of contract business is heard. A few factors are trying hard to encourage future business since they believe that prices will be fairly steady for some time to come. Manufacturers of crude products have done business on an increasing scale and prices have held steady. Consumers of intermediates are showing more interest in supplies and sellers realizing that there is more honest intention of buyers to come into the market to buy and not merely shop around are showing more disposition to meet buyers' views, and lower prices are being quoted among manufacturers as well as second hands.

Prices on *benzene* remained unchanged in producers' hands although reports were heard to the effect that business has picked up perceptibly. Quotations are made on the basis of 30@35c. per gal. for pure benzene in drums and tank cars. The 90 per cent grade is held at 28@32c. per gal. on the same basis. The increased business in this material has seemed to confine itself mostly to the 90 per cent grade, although some increase has been noted in the amount of business done in pure benzene. The market on *naphthalene* seems to be taking on some activity and with supplies scarce in second hands prices are holding steady. Resale lots of the ball variety were heard toward the close at 9½c. per lb., while flakes ranged from 8½@8½c. per lb. Producers' figures on flakes are quoted around 9@10c. per lb. and balls from 10@12c. Continued small lot buying of *phenol* has placed the spot market in an increasingly stronger position. The only stocks which are available in the open market are quite firmly held with most sellers asking as high as 11c. per lb. There seem to be small lots around at 10c. per lb., although these are becoming much harder to locate. Government surplus phenol is still offered at 12c. per lb.

The past week has shown the *aniline oil* market rather weak with available material easy and sellers offering as low as 20½c. per lb. Consumers are showing little disposition to take hold of any but small lots. Trading in *aniline salt* showed a tendency to improve with sales in a little larger volume. While supplies seem to be fairly easy, prices are more firmly held at 28@30c. per lb. Business in *beta-naphthol* below 33½c. per lb. seems to be impossible, but some sales were recorded at or near this figure. Quotations range from 33½c. up to 45c. per lb. according to seller. The spot lots of distressed material which have held the market in its recent weak position seem to be moving into stronger hands and the market is correspondingly firmer. The lowest price quoted at present by producers is 40c. per lb.

Prices on *paranitraniline* quoted by producers continue well above the spot market. Second hands offer stocks as low as 85c. per lb. with producers quoting up to \$1.05 per lb. There has been very little change in the quiet trading of *dimethylaniline*. Sellers are not pushing business very hard and it is not thought that much better than 55@60c. per lb. could be done. Sales of U. S. P. *salicylic acid* have been reported in the market at prices approaching the technical grade. Producers are quoting 22@23c. for the technical acid, but are doing little business at this figure. Quotations on *alpha-naphthylamine* have remained unchanged

on a dull market. Prices are variously given at 38@40c. per lb. according to seller. Business has been of such limited proportion that producers have not felt the necessity of bringing prices into better alignment.

WAXES

The demand for refined *beeswax* is reported good, but trading in the raw material has fallen off so that prices in some directions are barely steady. For the lower grade of crude beeswax prices range from 17@19c. per lb., depending upon color, quantity and seller. Refined wax is held at 27@35c. per lb. With little change in prices at primary points the market on *carnauba wax* was an uninteresting affair. Demand was described as routine. Offerings of the higher grades on spot were limited, but the common varieties appeared plentiful. No. 2 North Country grade closed unchanged at 18@19c. per lb. with the flora grade held at 70@71c. per lb.

Spot quotations for *Japan wax* were steady under moderate offerings and leading factors continued to quote from 19@20c. per lb. With the crude oil situation easier and no improvement in the export call the market for *paraffine wax* was unsettled throughout the week. Round lots of scale wax were offered by producers on the basis of 3½c. per lb. f.o.b. refinery without attracting any buyers. Refined wax of 130 degree melting point closed nominally at 6½c. per lb.

The Iron and Steel Market

PITTSBURGH, Feb. 25, 1921.

Conditions in the steel industry are working out in harmony with the theory stated in this report a week ago, that the price cutting produces no more business for the independent producers, and reduces the operation of the Steel Corporation. The price cutting has proceeded somewhat farther, but not much farther, chiefly because there is so little incentive by way of important inquiry coming out.

It is very doubtful whether the bookings of the independent mills, since the price cutting began, have been as heavy as they would have been if there had been no price cutting.

As to Steel Corporation operations there has been a very marked effect. It must be understood, of course, that the corporation's operations were marked for a decline, since at the beginning of the year many customers of the corporation were taking steel at a rate well beyond their current consumption, but the corporation's operations have been decreasing by reason of the price cutting much more rapidly than would otherwise have been the case. In the fore part of January the corporation operated at an average of about 92 per cent, measured in steel ingot production against rated capacity. Last week the corporation operated at not over 75 per cent and this week it is averaging not over 65 per cent. A somewhat similar rate of recession is to be expected in the next few weeks.

It is now rather generally understood that the independents, in cutting prices, did not expect to book any considerable tonnage of business, but hoped to produce eventually a redistribution of business, and expected to induce the Steel Corporation to reduce wages, as the majority of independents had already done, the reductions beginning in the fore part of last December. Effective February 16 the independents in the Youngstown district reduced wages and salaries generally by about 20 per cent. Yesterday the Jones & Laughlin Steel Company announced a similar reduction, effective March 1. These latest reductions involve, in the case of common labor, a reduction from 46 to 37 cents an hour.

STEEL CORPORATION FIRM

The United States Steel Corporation displays no indication whatever of being moved by these developments, in price and wage reductions. The corporation refuses to be stampeded, and that is certainly not remarkable in view of the truly spectacular performance of the corporation last year in refraining from advancing its prices when all the independents advanced and when the corporation's costs were somewhat increased by what occurred at independent mills, as well as by the wage advance of February 1 and the freight rate advance of August 26.

There is no question, of course, that the corporation will eventually reduce both prices and wages. The question is merely as to the time. No one has basis for predicting that the corporation will not wait months, although it is possible that action will be taken within a very short time.

INDEPENDENT DECLINES

Plainly defined declines in finished steel prices from the prices quoted a week ago are not particularly important. Plates can be done at \$3 a ton less, black sheets at \$1 a ton less and galvanized sheets at \$2 a ton less. Prices now quoted as the minimum of the open market, however, are probably in all cases subject to further discount in the event of a buyer offering an order sufficiently attractive in point of tonnage and specifications. Indeed, an outstanding feature of the attitude of some mills in quoting prices is that they do not represent the prices quoted as being a set minimum, but merely as being their price on the particular inquiry involved. The mills are careful to say nothing that might be interpreted by a possible buyer as a suggestion not to come back with other inquiries. Prices openly quotable, compared with Industrial Board or Steel Corporation prices, are now as follows: Bars, 2c. against 2.35c.; shapes, 2.20c. against 2.45c.; plates, 2.10c. against 2.65c.; plain wire, 3c. against 3.25c.; wire nails, \$3.10 against \$3.25; hoops, 2.85c. against 3.05c.; blue annealed sheets, 3.20c. against 3.55c.; black sheets, 4.10c. against 4.35c.; galvanized sheets, 5.25c. against 5.70c.

Tin plate remains firm at \$7 per base box, 100-lb. As for quite a while past there are offerings at second hand at deep cuts. Independent tin plate mills seem to be booking a trifle more business than formerly. The leading interest is in the third week of a four-week schedule of 70 per cent operation at its tin plate mills, and finds the operation involves the making of less stock than was expected, there being very fair shipments.

Standard steel pipe is not yet openly quotable at any decline, but some jobbers are selling at the mill price, and some other descriptions of welded steel tubular goods are going at concessions. Pipe mill operations are still heavy, even by the independents, pipe being quite different from all other finished steel commodities.

SEMI-FINISHED STEEL

Cut prices on sheet bars are now appearing freely. While the official price of the Steel Corporation is still \$47, independent mills have willingly quoted \$42 and it is reported one \$40 quotation has been made, but \$42 is merely the old Industrial Board price, the Steel Corporation having made a \$5 advance last September. Some sheet mills speak as if they might take hold at \$35, but in sheets as in some other lines the matter is still open whether the price of the raw material will make the price of the finished product, or the other way about. The market may be quoted nominal at \$42 for sheet bars and \$40 for billets.

PIG IRON AND COKE

As a result of a very few sales basic pig iron is quotable down \$2.50, to \$25, valley, and foundry down \$1, to \$27, valley. Bessemer by inference from basic drops from \$29, to \$27, valley. These prices are well below cost of production based on cost of ore piles, purchased at last season's ore prices, and well below the recent cost of coke. The furnaces merely do not know how much their ore piles have depreciated in value, that depending on prices that will be developed for the 1921 ore season. As to coke, operators will sell at flat prices, below those that would be dictated by contracts now nominally in force, a typical contract being at 5 to 1 against basic pig iron, but with a \$5.75 minimum, so that when basic iron declined below \$28.75 the minimum would obtain instead of the ratio. One could buy at \$5 and perhaps at less, certainly at much less if wages in the coke region were reduced. That seems to await action by the Steel Corporation on the general subject of wages, the independent operators in the Connellsville region being indisposed to act except under leadership of the Frick company.

Potassium muriate..... ton	67.00 — 70.00	
Potassium iodide..... lb.		2.75 — 3.00
Potassium nitrate..... lb.	.09½ — .09½	.10 — .12½
Potassium permanganate..... lb.	.45 — .46	.48 — .50
Potassium prussiate, red..... lb.	.50 — .52	.53 — .55
Potassium prussiate, yellow..... lb.	.28 — .29	.30 — .32
Potassium sulphate (powdered)..... per unit		— 2.25
Rochelle salts (see sodium potassium tartrate)		
Salammoniac (see ammonium chloride)		
Sal soda (see sodium carbonate)		
Salt cake..... ton		32.00 — 33.00
Silver cyanide..... oz.		1.25 — 1.40
Silver nitrate..... oz.		.40½ — .41½
Soda ash, light..... 100 lb.	2.00 — 2.10	2.20 — 2.50
Soda ash, dense..... 100 lb.	2.20 — 2.30	2.40 — 2.60
Sodium acetate..... lb.	.05½ — .05½	.06 — .06½
Sodium bicarbonate..... 100 lb.	2.50 — 2.75	3.00 — 3.25
Sodium bichromate..... lb.	.08½ — .08½	.09 — .09½
Sodium bisulphate (nitre cake)..... ton	7.00 — 7.50	8.00 — 11.00
Sodium bisulphate, powdered, U.S.P..... lb.	.05 — .05½	.06 — .06½
Sodium borate (borax)..... lb.	.08½ — .08½	.08½ — .09
Sodium carbonate (sal soda)..... 100 lb.	2.00 — 2.25	2.50 — 2.75
Sodium chl rate..... lb.	.10 — .10½	.10½ — .11
Sodium cyanide, 96-98 per cent..... lb.	.18 — .19	.20 — .28
Sodium fluoride..... lb.	.13 — .14	.14½ — .15
Sodium hydroxide (caustic soda)..... 100 lb.	3.70 — 3.80	3.90 — 4.10
Sodium hyposulphite..... lb.		.03½ — .04
Sodium nitrate..... 100 lb.	2.85 — 3.00	3.00 — 3.10
Sodium nitrite..... lb.	.06 — .06½	.06½ — .07
Sodium peroxide, powdered..... lb.	.30 — .31	.32 — .34
Sodium phosphate, dibasic..... lb.	.04 — .04½	.04½ — .05
Sodium potassium tartrate (Rochelle salts) lb.		.29 — .31
Sodium prussiate, yellow..... lb.	.15½ — .15½	.15½ — .16
Sodium silicate, solution (40 deg.)..... lb.	1.10 — 1.15	1.20 — 1.40
Sodium silicate, solution (60 deg.)..... lb.	.02½ — .03	.03½ — .03½
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.75 — 2.00	2.25 — 2.50
Sodium sulphide, crystal, 60-62 per cent (conc.) lb.	.05 — .05½	.05½ — .06
Sodium sulphite, crystals..... lb.	.04 — .04½	.04½ — .05
Strontium nitrate, powdered..... lb.	.16 — .16½	.16½ — .17
Sulphur chloride, red..... lb.	.07 — .07½	.07½ — .08
Sulphur, crude..... ton	16.00 — 20.00	
Sulphur dioxide, liquid, cylinders..... lb.	.08 — .08½	.08½ — .09
Sulphur (sublimed), flour..... 100 lb.		2.25 — 3.10
Sulphur, roll (brim tone)..... 100 lb.		2.00 — 2.75
Tin bichloride, 50 per cent..... lb.	.18 — .19	
Tin oxide..... lb.		.45 — .47
Zinc carbonate, precipitate..... lb.	.16 — .18	.19 — .20
Zinc chloride, gran..... lb.	.11 — .11½	.11½ — .12
Zinc cyanide..... lb.	.45 — .49	.50 — .60
Zinc dust..... lb.	.12 — .13	.13½ — .14
Zinc oxide, XX..... lb.	.08½ — .09	.09½ — .11
Zinc sulphate..... lb.	.03½ — .03½	.04 — .06

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.10 — \$1.15
Alpha-naphthol, refined..... lb.	1.45 — 1.50
Alpha-naphthylamine..... lb.	.38 — .40
Aniline oil, drums extra..... lb.	.20½ — .26
Aniline salts..... lb.	.27 — .30
Anthracene, 80% in drums (100 lb.)..... lb.	.75 — 1.00
Benzaldehyde U.S.P..... lb.	1.00 — 1.50
Benzidine, base..... lb.	.95 — 1.05
Benzidine sulphate..... lb.	.80 — .90
Benzoic acid, U.S.P..... lb.	.70 — .75
Benzoate of soda, U.S.P..... lb.	.70 — .80
Benzene, pure, water-white, in drums (100 gal.)..... gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)..... gal.	.28 — .32
Benzyl chloride, 95-97%, refined..... lb.	.30 — .35
Benzyl chloride, tech..... lb.	.25 — .30
Beta-naphthol benzoate..... lb.	3.50 — 4.00
Beta-naphthol, sublimed..... lb.	.70 — .75
Beta-naphthol, tech..... lb.	.33½ — .40
Beta-naphthylamine, sublimed..... lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)..... lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums..... gal.	.95 — 1.00
Cresylic acid, 75-97%, dark, in drums..... gal.	.90 — .95
Cresylic acid, 50%, first quality, drums..... gal.	.60 — .65
Dichlorobenzene..... lb.	.06 — .09
Diethylaniline..... lb.	1.20 — 1.30
Dimethylaniline..... lb.	.55 — .65
Dinitrobenzene..... lb.	.30 — .32
Dinitrochlorobenzene..... lb.	.25 — .30
Dinitronaphthalene..... lb.	.33 — .35
Dinitrophenol..... lb.	.40 — .45
Dinitrotoluene..... lb.	.25 — .30
Dip oil, 25%, tar acids, car lots, in drums..... gal.	.38 — .40
Diphenylamine..... lb.	.60 — .70
H-acid..... lb.	1.30 — 1.50
Meta-phenylenediamine..... lb.	1.25 — 1.30
Monochlorobenzene..... lb.	.14 — .16
Monoethylaniline..... lb.	1.75 — 2.00
Naphthalene crushed, in bbls. (250 lb.)..... lb.	.08 — .08½
Naphthalene, flake..... lb.	.08½ — .08½
Naphthalene, balls..... lb.	.09½ — .10
Naphthionic acid, crude..... lb.	.70 — .75
Nitrobenzene..... lb.	.12 — .15
Nitro-naphthalene..... lb.	.30 — .35
Nitro-toluene..... lb.	.18 — .25
Ortho-amidophenol..... lb.	3.20 — 3.75
Ortho-dichlor-benzene..... lb.	.15 — .20
Ortho-nitro-phenol..... lb.	.75 — .80
Ortho-nitro-toluene..... lb.	.20 — .24
Ortho-toluidine..... lb.	.25 — .30
Para-amidophenol, base..... lb.	1.90 — 2.00
Para-amidophenol, HCl..... lb.	2.10 — 2.20

Para-dichlorobenzene..... lb.	.15 — .25
Paranitroaniline..... lb.	.85 — 1.00
Para-nitrotoluene..... lb.	.90 — 1.05
Para-phenylenediamine..... lb.	1.90 — 2.00
Para-toluidine..... lb.	1.30 — 1.60
Phthalic anhydride..... lb.	.55 — .60
Phenol, U. S. P., drums (dest.), (240 lb.)..... lb.	.10 — .12
Pyridine..... gal.	2.00 — 3.50
Resorcinol, technical..... lb.	1.85 — 2.00
Resorcinol, pure..... lb.	2.30 — 2.50
Salicylic acid, tech., in bbls. (110 lb.)..... lb.	.22 — .23
Salicylic acid, U. S. P..... lb.	.25 — .27
Salol..... lb.	.85 — .95
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.28 — .31
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.15 — .18
Sulphanilic acid, crude..... lb.	.30 — .35
Tolidine..... lb.	1.35 — 1.45
Toluidine, mixed..... lb.	.40 — .45
Toluene, in tank cars..... gal.	.28 — .32
Toluene, in drums..... gal.	.31 — .35
Xylidine, drums, 100 gal..... lb.	.40 — .45
Xylene, pure, in drums..... gal.	.42 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 — \$0.26
Beeswax, refined, light..... lb.	.27 — .28
Beeswax, white pure..... lb.	.40 — .45
Carnauba, Fla..... lb.	.70 — .71
Carnauba, No. 2, North Country..... lb.	.30 — .32
Carnauba, No. 3, North Country..... lb.	.18 — .19
Japan..... lb.	.19 — .20
Montan, crude..... lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04½ — .04½
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.03½ — .03½
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 — .05
Paraffine waxes, refined, 125 m.p..... lb.	.05½ — .05½
Paraffine waxes, refined, 128-130 m.p..... lb.	.06½ — .06½
Paraffine waxes, refined, 133-135 m.p..... lb.	.07½ — .07½
Paraffine waxes, refined, 135-137 m.p..... lb.	.08½ — .09
Stearic acid, single pressed..... lb.	.12 — .12
Stearic acid, double pressed..... lb.	.12½ — .12½
Stearic acid, triple pressed..... lb.	.13½ — .13½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.70
Pine oil, pure, dest. dist..... gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970..... gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.37
Pinewood creosote, ref..... gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-..... bbl.	280 lb.	\$6.75 —
Rosin E-I..... bbl.	280 lb.	6.75 —
Rosin K-N..... bbl.	280 lb.	6.75 —
Rosin W. G.-W. W..... bbl.	280 lb.	7.00 —
Wood rosin, bbl..... bbl.	280 lb.	7.25 —
Spirits of turpentine..... gal.		.56 —
Wood turpentine steam dist..... gal.		.54 —
Wood turpentine, dest. dist..... gal.		.53 —
Pine tar pitch, bbl..... 200 lb.		8.50 —
Tar, kiln burned, bbl. (500 lb.)..... bbl.		15.00 —
Retort tar, bbl..... 500 lb.		15.00 —
Rosin oil, first run..... gal.		.50 —
Rosin oil, second run..... gal.		.52 —
Rosin oil, third run..... gal.		.60 —

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0.17 — \$0.18
Upriver coarse..... lb.	.13 — .14
Upriver caucho ball..... lb.	.14 — .14½
Plantation—First latex crepe..... lb.	.19½ — .19½
Ribbed smoked sheets..... lb.	.18½ — .18½
Brown crepe, thin, clean..... lb.	.18 — .18
Amber crepe No. 1..... lb.	.20 — .20

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.09 — \$0.09½
Castor oil, AA, in bbls..... lb.	.10 — .10½
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.08 — .08½
Cocoonut oil, Ceylon grade, in bbls..... lb.	.11½ — .11½
Cocoonut oil, Cochon grade, in bbls..... lb.	.11½ — .12
Cori oil, crude, in bbls..... lb.	.08½ — .09
Cottonseed oil, crude (f. o. b. mill)..... lb.	.05½ — .05½
Cottonseed oil, summer yellow..... lb.	.07 — .07½
Cottonseed oil, winter yellow..... lb.	.08 — .08½
Linseed oil, raw, car lots (domestic)..... gal.	.67 — .68
Linseed oil, raw, tank cars (domestic)..... gal.	.60 — .60
Linseed oil, boiled, car lots (domestic)..... gal.	.69 — .70

Olive oil, commercial.....	gal.	\$2.60	—	\$2.75
Palm, Lagos.....	lb.	.07½	—	.07¾
Palm, Niger.....	lb.	.06½	—	.06¾
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.06½	—	.06¾
Peanut oil, refined, in bbls.....	lb.	.12½	—	.13
Rapeseed oil, refined in bbls.....	gal.	1.05	—	1.10
Rapeseed oil, blown, in bbls.....	gal.	1.15	—	1.20
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07½	—	.07¾
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04½	—	

FISH

Light pressed menhaden.....	gal.	\$0.46	—	\$0.48
Yellow bleached menhaden.....	gal.	.48	—	.50
White bleached menhaden.....	gal.	.50	—	.52
Blown menhaden.....	gal.	.85	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—	
Blanc fixe, dry.....	lb.	.05	—	.05½
Blanc fixe, pulp.....	net ton	50.00	—	60.00
Casein.....	lb.	.14	—	.16
Chalk, domestic, extra light.....	lb.	.05	—	.05½
Chalk, domestic, light.....	lb.	.04½	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04½	—	.05
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (kaolin), imported, lump.....	net ton	23.00	—	25.00
China clay (kaolin), imported, powdered.....	net ton	30.00	—	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mires.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Fla.....	net ton	25.00	—	
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	35.00	—	40.00
Graphite, crucible, 90% carbon, Ashland, Ala.....	lb.		—	.09
Graphite, crucible, 85% carbon, Ashland, Ala.....	lb.	.07	—	.09
Graphite, higher lubricating grades.....	lb.	.11	—	.40
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic lump.....	lb.	.05	—	.05½
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.65	—	
Shellac, orange superfine.....	lb.	.70	—	
Shellac, A. C. garnet.....	lb.	.57	—	
Shellac, T. N.....	lb.	.55	—	
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	14.00	—	15.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	40.00	—	50.00
Talc, California talcum powder grade.....	ton	20.00	—	45.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	160	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	80-100	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	45- 50	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton	- 55	
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	55- 60	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	45- 50	
Magnesite brick, 9-in. straight.....	net ton	100	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	105	
Magnesite brick, soaps and splits.....	net ton	120	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	65- 70	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	56- 61	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	50- 60	

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.16	—	
Ferrochrome, per lb. of Cr. contained, 4-6% carbon, carlots.....	lb.	.16	—	.17
Ferromanganese, 76-80% Mn, domestic.....	gross ton	95.00	—	100.00
Ferromanganese, 76-80% Mn, English.....	gross ton	95.00	—	100.00
Spiegelisen, 18-22% Mn.....	gross ton	38.00	—	40.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.00	—	2.50
Ferrosilicon, 10-15%.....	gross ton	50.00	—	55.00
Ferrosilicon, 50%.....	gross ton	80.00	—	85.00
Ferrosilicon, 75%.....	gross ton	150.00	—	155.00
Ferrotungsten, 70-80%, per lb. of contained W.....	lb.	.55	—	.60
Ferrouanium, 35-50% of U, per lb. of U content.....	lb.	7.00	—	
Ferrovandium, 30-40% per lb. of contained V.....	lb.	5.00	—	5.25

Ores and Semi-finished Products

All f.o.b. New York, Unless Otherwise Stated

Bauxite, 52% Al content, less than 2% Fe ₂ O ₃ , up to 20% silica, not more than H 4% moisture.....	gross ton	\$10.00	—	\$11.00
Chrome ore, Calif. concentrates, 50% min. Cr ₂ O ₃	unit	.55	—	.60
Chrome ore, 50% Cr ₂ O ₃ , f.o.b. Atlantic seaboard.....	unit	50	—	55
Coke, foundry, f.o.b. ovens.....	net ton	6.00	—	6.50
Coke, furnace, f.o.b. ovens.....	net ton	5.00	—	5.50
Coke, petroleum, refinery, Atlantic seaboard.....	net ton	16.00	—	17.00
Fluorspar, lump, f.o.b. Heathden, New Mexico.....	net ton	17.50	—	
Fluorspar, standard, domestic washed gravel Kentucky and Illinois mines.....	net ton	22.50	—	25.00
Ilmenite, 52% TiO ₂ , per lb. ore.....	lb.	.01½	—	.01¾
Manganese ore, 50% Mn, c.i.f. Atlantic seaport.....	unit	.40	—	.45
Manganese ore, chemical (MnO ₂).....	gross ton	60.00	—	65.00
Molybdenite, 85% MoS ₂ , per lb. of MoS ₂ , N. Y.....	lb.	.55	—	.60
Monazite, per unit of ThO ₂ , c.i.f., Atlantic seaport.....	unit	30.00	—	
Pyrites, Spanish, fines, c.i.f., Atlantic seaport.....	unit	.16	—	
Pyrites, Spanish, furnace size, c.i.f. Atlantic seaport.....	unit	.16½	—	
Pyrites, domestic, fines, f.o.b. mines, Ga.....	unit	.12	—	.14
Rutile, 95% TiO ₂ per lb. ore.....	lb.	.15	—	
Tungsten, scheelite, 60% WO ₃ and over, per unit of WO ₃ (nominal).....	unit	3.00	—	3.25
Tungsten, Wolframite, 60% WO ₃ and over, per unit of WO ₃ , N. Y. C.....	unit	3.00	—	3.25
Uranium ore (carnotite) per lb. of U ₃ O ₈	lb.	1.50	—	2.50
Uranium oxide, 96% per lb. contained U ₃ O ₈	lb.	2.25	—	2.50
Vanadium pentoxide, 99%.....	lb.	12.00	—	14.00
Vanadium ore, per lb. of V ₂ O ₅ contained.....	lb.	1.50	—	
Zircon, washed, iron free.....	lb.	.03	—

*Add 10c per 100 lb. for trucking to Jersey City and 15c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

HUNTSVILLE—The F. & O. Cedar Works, specializing in the manufacture of cedar and other oils, is planning for the rebuilding of its plant, recently destroyed by fire. Lucien Hewlett is manager.

Arkansas

BATESVILLE—The Planters' Lime, Phosphate & Fertilizer Co., recently organized with a capital of \$1,500,000, is planning for the erection of a new plant for the production of hydrated lime and other lime products, with department of the works devoted to the manufacture of fertilizer. The company has a large tract of property in this section. J. R. Alexander, Scotts, Ark., is president; J. W. Williamson, Batesville, is secretary.

California

SAN FRANCISCO—The General Petroleum Co., 310 Sansome Street, has arranged for a note issue of \$7,500,000, the proceeds to be used, in part, for proposed extensions in refineries, improvements, and general expansion.

BURBANK—The Empire China Co. has commenced the erection of a new plant, consisting of three one-story, brick factories, 140 x 318 ft., 32 x 318 ft., and 24 x 125 ft., respectively. The works will be used for the manufacture of chinaware, porcelain, etc., and is estimated to cost about \$80,000. Farley & Farley, Burbank, have the construction contract.

LOS ANGELES—The Pacific Clay Products Co., American Bank Building, has preliminary plans under way for the construction of an addition to its plant at Los Nietos, near Whittier, to be used for the manufacture of brick and other burned clay products. The first unit will have a capacity of 25,000 bricks per day to be supplemented later with a second unit of about 15,000 daily output.

Delaware

WILMINGTON—The Martin Leather Co. has acquired the former leather works of Barr & Dougherty, 707 East Fifth St., more recently owned by the Standard Kid Mfg. Co., for a consideration said to be about \$90,000. The new owner will improve the works, with the installation of new equipment as required. Production will be inaugurated on a small scale and increased as soon as conditions warrant.

Florida

MIAMI—The Standard Poured Brick Co. is planning for the erection of a large addition to its plant in the Miami Canal district, increasing the present output of about 5,000 bricks per day to 50,000 bricks daily.

WEST PALM BEACH—W. J. Carroll, P. O. Box 611, and associates, have plans under way for the construction of a new glass manufacturing plant. A site has been selected and machinery will be purchased at an early date.

Georgia

SAVANNAH—The Southern Fertilizer & Chemical Co. will inaugurate operations at once at its new local plant, recently completed. The new factory represents an investment of close to \$1,000,000 and will replace the company's works at Hutchinson Island, destroyed by fire in 1920. The new plant will specialize in the manufacture of finished fertilizer, with large department devoted to the production of acid phosphate. The production of the company's works at St. Mary's, Ga., and Philadelphia, Pa., will be utilized at the new factory.

METTER—The Metter Naval Stores Co. has preliminary plans under way for the construction of a new turpentine manufacturing plant in the vicinity of Register, Ga., to cost about \$23,000.

Maryland

BALTIMORE—The Zirconium Co. of America, recently organized under state laws to manufacture ferrozirconium, zirconium oxide, and other refractory products, has acquired the property of the Baltimore Rubber Tire Mfg. Co., Monument and Eleventh Streets, consisting of about 2½ acres of land and 6 factory buildings. The present structures will be remodeled and improved, and equipped for the manufacture of the new line. It is proposed to commence operations at an early date. The company is headed by George F. Dixon, president; Philip C. Spencer, vice-president; Morris Meyer, treasurer; and Charles W. Smiley, 1622 Smallwood Street, secretary.

Massachusetts

EAST BRIDGEWATER—The Old Colony Foundry Co., Cook Street, will break ground early in March for the erection of an addition to its plant. Plans are now being prepared. Improvements will also be made in the present building. Charles L. Nutter is treasurer.

SPRINGFIELD—The United States Envelope Co., manufacturer of paper specialties, is arranging for the early occupancy of its new four-story plant addition now nearing completion. The factory with machinery is estimated to cost about \$400,000.

Minnesota

MINNEAPOLIS—The plant of the Minneapolis Paper Supply was destroyed by fire, Feb. 20, with loss estimated at about \$450,000, including equipment. The company is reported to be planning for the rebuilding of the works.

MINNEAPOLIS—The Twin City Separator Co., 2830 Colfax Avenue, manufacturer of separating equipment for mechanical service, has plans under way for the erection of a one-story addition to be located at Seventeenth and Madison Sts. C. O. Paulson is secretary and treasurer.

Michigan

SAGINAW—The Standard Oil Co., 910 South Michigan Avenue, Chicago, Ill., has preliminary plans under way for the erection of a new 2-story and basement building at Saginaw, 75 x 150 ft., to cost about \$100,000.

New Jersey

NEWARK—The Ocean Leather Co., Inc., 33 New York Ave., has plans under way for the erection of a new plant in the vicinity of Beaufort, S. C., for converting the skins of sharks and other sea monsters into leather. A large reduction works will be established in connection with the plant.

North Carolina

GLENDON—The Talc Products Co., 7-9 Hanover Street, New York, N. Y., has plans under way for the construction of a new plant at Glendon. The company has a tract of about 200 acres of talc deposits, and the new plant will have an initial output of about 100 tons per day. A grinding plant will be installed. Charles A. Breiting is manager.

Ohio

BALTIMORE—The Fairfield Paper Box Co. has awarded a contract to the H. K. Ferguson Co., 6523 Euclid Ave., Cleveland, Ohio, for the erection of a new 2-story factory, with power house, at Delaware, Ohio, to cost about \$160,000 with machinery. The works will consist of a paper mill and paper box factory. T. D. Griley is manager.

DAYTON—The Refinera Oil Co., 315 South Main St., is having plans prepared for the erection of a new 1- and 2-story building on South Ludlow St. R. S. King is president.

WILLARD—The Pioneer Rubber Co. is having plans prepared for the erection of an addition to its plant to cost about \$50,-

000, to be 2-story, 60 x 160 ft. A number of homes for employees at the plant will also be constructed at an approximately like cost. B. O. Smith is president.

Oklahoma

YALE—The Buffalo Refining Co., recently organized, is planning for the erection of a new oil refinery with initial capacity of about 1,500 bbl. per day. G. W. Lillie is president, and Edward M. Weist, secretary and general manager.

Oregon

EUGENE—The Studebaker Rubber Co., Spokane, Wash., is negotiating for a local site for the erection of a new plant for the manufacture of automobile tires and other rubber products.

Pennsylvania

PHILADELPHIA—Fire, Feb. 17, at the plant of the Atlantic Refining Co., Thirty-fifth St. and River Road, caused a loss of about 100,000 gal. of oil and considerable equipment, including coke stills, etc. No official estimate of amount of loss has been made.

PHILADELPHIA—The Pennsylvania Wire Glass Co., Pennsylvania Bldg., is completing plans for the erection of its proposed new plant at Lewistown, Pa., to consist of a number of buildings of different sizes. It is expected to call for estimates at an early date.

South Carolina

CARLISLE—The Carlisle Cotton Oil Co. is planning for the rebuilding of its local plant, recently destroyed by fire.

Texas

EL PASO—The International Fiber Co., 610 Caples Bldg., recently organized with a capital of \$500,000, has acquired a local building for its initial works, to be used for the manufacture of fiber specialties from certain kind of cacti. Equipment will be installed at once, including machine shop apparatus. At a later date the company proposes to build a new plant in this section. W. J. Rand is president.

GALVESTON—The Ribbon Works, Inc., recently organized to manufacture ribbons for writing and adding machines, etc., will establish a chemical and dye works in connection with its proposed new plant. Carbon-coating machinery for the manufacture of carbon papers, and other kindred equipment will be installed. J. D. Claitor is president and manager.

UVALDE—W. A. White, P. O. Box 247, and associates, have plans under way for the establishment of a new local plant for the manufacture soap products. A list of equipment to be installed will be arranged at an early date.

Virginia

LYNCHBURG—The Lynchburg Glass Works is planning for extensions and improvements in its plant for increased production. New machinery will be installed.

RICHMOND—The Phospho-Germ Mfg. Co., manufacturer of fertilizer, has completed plans for the erection of a new plant 65 x 76 ft., to be equipped for general manufacture. The plant will replace a factory recently destroyed by fire.

West Virginia

ROUND BOTTOM—H. J. Booth, Pittsburgh, Pa., is organizing a company to build a new plant here for the manufacture of glass products. Preliminary details of the factory are being arranged.

Washington

VANCOUVER—The Johnson Metal Refining Co. has filed plans for extensions and improvements in its plant. A new tinning works will be established.

ANACORTES—Plans are under way for the resumption of operations at the Anacortes Glass Co. plant. The works have been shut down for some time and a committee is obtaining funds through local subscriptions for remodeling and improving the factory, including the installation of new equipment.

SEATTLE—The General Basic Products Co., Harbor Island, is having plans prepared for the erection of a new four-story plant to be located on the East Marginal Way. Bids for construction and equipment will be asked at an early date. Henry Bittman, Securities Building, is architect and engineer.

Capital Increases, Etc.

THE COLONIAL CHEMICAL CORP., Reading, Pa., has filed notice of increase in its capital from \$50,000 to \$250,000 for financing and expansion.

THE LILLY VARNISH CO., Indianapolis, Ind., has filed notice of increase in its capital from \$100,000 to \$250,000 for general expansion.

THE ROCO CHEMICAL CO., Lawrenceburg, Ind., has filed notice of change of name to the Rossville Chemical Co.

THE WESTERN GLASS CO., Streator, Ill., manufacturer of glass products, has filed notice of increase in capital from \$250,000 to \$1,000,000.

THE PIEDMONT, MOUNT AIRY GUANO CO., Keyser Bldg., Baltimore, Md., manufacturer of fertilizer products, has increased its capital to \$1,000,000. E. W. Levering is president.

THE CONNECTICUT OIL CO., Waterbury, Conn., has increased its outstanding capital to an amount of \$95,150.

THE NEW MARTINSVILLE GLASS & MFG. CO., New Martinsville, W. Va., has increased its capital from \$100,000 to \$150,000. Ira Clarke is manager.

THE STANDARD METALS REFINING CO., South Bend, Ind., has filed notice of increase in capital from \$50,000 to \$75,000.

THE SARGENT PAINT CO., Indianapolis, Ind., has filed notice of increase in capital from \$75,000 to \$200,000.

THE PORTLAND CEMENT PRODUCT CO., La Salle, Ill., has filed notice of dissolution under state laws.

THE CHICAGO WRAPPER BOX & LABEL CO., Chicago, Ill., has filed notice of change of name to the Chicago-Elgin Carton Co., at the same time increasing its capital from \$10,000 to \$30,000.

New Companies

THE INDEPENDENT OIL & SUPPLY CO., 140 West Van Buren St., Chicago, Ill., has been incorporated with a capital of \$15,000 to manufacture vegetable oils, etc. The incorporators are M. L. Coleman, Edward R. Drake, George N. Vail.

THE CO-OPERATIVE PHOSPHATE CO., Mulberry, Fla., has been incorporated with a capital of \$500,000 to operate phosphate properties, manufacture fertilizers, etc. The incorporators are L. N. Pipkin, H. W. Wear and A. D. West, Mulberry.

THE O-C-T SECTIONAL TIRE & RUBBER CO., Kansas City, Mo., has been incorporated under Delaware laws with a capital of \$1,000,000 to manufacture automobile tires and other rubber products. The incorporators are James B. O'Connor, Lawson Tarwater and S. L. Carter, all of Kansas City.

THE PROGRESSIVE VARNISH WORKS, 2458 E. 24th St., Los Angeles, Cal., has filed notice of organization to manufacture paints, varnish, oils, etc. The company is headed by Osmond Olsen and Albert Sail-and.

A. F. LUCATI & CO., INC., New York, has been incorporated with a capital of \$15,000 to manufacture chemicals and byproducts. The incorporators are C. Vignone, A. Barratta and A. Lucati, 23 W. 8th St.

THE HANSA CO., INC., Hoboken, N. J., has been incorporated with a capital of \$30,000 to manufacture chemical products. The incorporators are M. Dillon, Thomas M. and William S. Stuhr, Hoboken.

THE KALBFLEISCH CORP., 31 Union Sq., New York, has been incorporated under Delaware laws with capital of \$7,500,000 to manufacture chemicals and byproducts.

THE PAUL J. KREZ CO., 444 North La Salle St., Chicago, Ill., has been incorporated with a capital of 250 shares of stock, no par value, to manufacture asbestos, Magnesia and kindred products. The incorporators are Paul J. and John J. Krez, and Michael Koch.

THE SODIPHENE CO., 928 Central Ave., Kansas City, Mo., has been incorporated with a capital of \$200,000 to manufacture chemical products. The incorporators are R. M. Seibel, B. A. Parsons and H. C. Campbell.

THE CONTINENTAL PAPER GRADING CO., 1451 South Peoria Street, Chicago, Ill., has been incorporated with a capital of \$50,000 to manufacture paper products. The incorporators are Edward L. Kennedy, Arnold Epstein and Isaac Sanderff.

THE HOME LEATHER CO., INC., Detroit, Mich., has been incorporated with a capital of \$50,000 to manufacture leather goods, findings, etc. The incorporators are Anton Martin, Olin A. Bullock and Vincent Elias,

337 East Farnum Street, Royal Oak, Detroit.

THE ENTLE & MUDGE CO., Feller's Hall Building, Martinsburg, W. Va., has been incorporated with a capital of \$35,000 to manufacture paints, varnishes, etc. The incorporators are E. E. Entler, George E. Mudge and A. H. Stanley.

THE EAGLE PAINT & VARNISH WORKS, Brooklyn, N. Y., has been incorporated with a capital of \$50,000 to manufacture paints, varnishes, oils, etc. The incorporators are M. R. Hillman, M. A. Plunkett and W. S. Rising, 1082 East Thirty-seventh Street, Brooklyn.

THE KIMMEL GLASS CO., Paterson, N. J., has been incorporated with a capital of \$100,000 to manufacture glass products. The incorporators are Paul Wolff, S. and Hyman Kimmel, 14 West Street.

THE CLARK RUBBER CO., Franklin, Mass., has been incorporated with a capital of \$100,000 to manufacture rubber products. The incorporators are Maurice C. Clark, Herbert L. Metcalfe and Leon B. Conant, Franklin.

THE BUILDERS' PAINT CO., Okmulgee, Okla., has been incorporated with a capital of \$10,000 to manufacture paints, varnishes, etc. The incorporators are Carl Barnhart and O. J. Trussell, Okmulgee; and M. A. Oxley, Kansas City, Mo.

THE SPECIAL PRODUCTS CO., Boston, Mass., has been incorporated with a capital of \$100,000 to manufacture chemicals and affiliated products. The incorporators are James R. Emmett, Justin Edwards and Arthur L. Norton, 113 High Street.

THE MERIT GLASS CO., New York, has been incorporated with a capital of \$10,000 to manufacture glass specialties. The incorporators are A. L. Gaston, S. Kirschner and J. J. Friedman, 925 St. Nicholas Avenue.

THE RADIO X. SUPPLY CO., Detroit, Mich., has been incorporated with a capital of \$50,000 to manufacture radio and chemical compounds and preparations. The incorporators are H. F. Carpenter, R. C. Burns and J. C. Hoover, 205 Woodward Avenue.

THE MARYLAND LIME MARL CO., Hagerstown, Md., has been incorporated with a capital of \$75,000 to manufacture lime and affiliated products. The incorporators are Henry E. Bester, Frank D. Adams and Thomas L. Smith, Hagerstown.

THE M. C. CORNEZ LEATHER CO., INC., Boston, Mass., has been incorporated with a capital of \$25,000 to manufacture leather products. The incorporators are R. C. Cornez, Archie E. Balter, and M. C. Cornez, 16 Parkman Street, Brookline, Mass.

THE REFINERS' PETROLEUM CO., 220 South State Street, Chicago, Ill., has been incorporated with a capital of \$25,000 to manufacture refined petroleum products. The incorporators are H. A., G. S., and O. H. McCornack.

THE TRAXOL CO., 415 North Cicero Avenue, Chicago, Ill., has been incorporated with a capital of \$6,000 to manufacture chemicals and drugs. The incorporators are D. and Charles A. Treckman, and Harry Goldberg.

THE ATLAS RUBBER CO., 912 Third Avenue, Huntington, W. Va., has been incorporated with a capital of \$5,000 to manufacture rubber products. The incorporators are E. F. Hartley, C. L. Hibner and E. A. Jordan.

THE WELLSBORO SHALE BRICK CO., Wellsboro, Pa., has been incorporated with a capital of \$20,000 to manufacture brick, tile and kindred products. The incorporators are Emil E. Rose, Toledo, Ohio, and associates.

THE MAXINE CO., Connersville, Ind., has been incorporated with a capital of \$50,000 to manufacture chemicals and affiliated products. The incorporators are M. R. C. McKennan, and M. B. Murray.

ALEXANDER FRASER, INC., Oldtown, Me., has been incorporated with a capital of \$50,000 to manufacture chemicals, drugs and affiliated products. The incorporators are Alexander Fraser and N. O'Connell, Oldtown.

THE BECKER-TABB PAINT CO., Louisville, Ky., has been incorporated with a capital of \$20,000 to manufacture paints, varnishes, etc. The incorporators are C. H. Becker, J. Preston Tabb and John Manly.

THE LOCKPORT DEOXIDIZED BRONZE & METAL CO., Lockport, N. Y., has been incorporated with a capital of \$30,000 to manufacture bronze and brass products, metal alloys, etc. The incorporators are P. K. Haber, J. Zaluski and J. C. Rock, Lockport.

THE W. D. YOUNG CO., Boston, Mass., has been incorporated with a capital of \$75,000

to manufacture chemicals, drugs, and kindred products. The incorporators are Harry D. Evans, Guy A. Ham, and Harold P. Newell, 947 Boylston Street, Newton, Mass.

THE SOUTHERN CEDAR OIL CO., 1759 West Forty-eighth Street, Chicago, Ill., has been incorporated with a capital of \$40,000 to manufacture oil products. The incorporators are Walter J. Warczak and Frank A. Kolesiak.

THE WALLACE PETROLEUM CO., Huntington, W. Va., has been incorporated with a capital of \$50,000 to manufacture petroleum products. The company will operate in the vicinity of Louisa, Ky. The incorporators are M. E. Griffin, G. R. Jackson, Huntington; and F. D. T. Wallace, Jr., Louisa.

THE GRANADA SYRUP & SUGAR CO., Plaquemine, La., has been incorporated with a capital of \$125,000 to operate a sugar mill. The incorporators are Oscar Richard, Sr., Sunshine, La.; and Edmund Becnell, Plaquemine.

S. L. CALECHMAN & SON, INC., New York, has been incorporated with a capital of \$25,000 to manufacture chemicals and chemical compounds. The incorporators are S. L. Calechman, G. C. Stickleck and S. Glick, 20 West Ninety-sixth Street.

Coming Meetings and Events

AMERICAN CERAMIC SOCIETY, CHICAGO SECTION, plans to hold a joint meeting with the Illinois Clay Manufacturers Association of Chicago about March 8.

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CANADIAN INSTITUTE OF MINING AND METALLURGY is holding its annual general meeting in the Chateau Laurier, Ottawa, Ont., March 2, 3 and 4.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon April 26 at Rochester, N. Y., for luncheon.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27, 28 and 29.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

The Great Cemetery Of Archives

IN A late number of *Science* Prof. HERDMAN F. CLELAND suggests that information about places in the United States which is available in Washington be also made available in the places themselves. The idea is so reasonable that anyone might well blush to say that he didn't think of it before.

Dr. CLELAND, who is a geologist, gives some instances which speak for themselves. At Uvalde, Tex., he observes, there are interesting volcanic necks which are all mapped and described in a United States Geological Survey folio, but when he went there to study the formations there was no folio available or within reach. At Ardmore, Okla., he wished to consult the geological literature of that region, but at the Carnegie Library he found neither the state publications nor the excellent professional paper of the United States Survey of the district. The same holds true of most of the scientific data, obtained at great labor and expense by the Government, of the country and for (it would seem) the records at Washington.

Now there's no use in blaming Washington for this. Society at Uvalde, for instance, or Ardmore, is probably more interested in the beautiful columnar throats described in the best sellers in fiction than it is in volcanic necks, and the librarian of the local storehouse of literature can truthfully say that there isn't any call for books on geology, or botany, or biology.

But why hold Uvalde or Ardmore up to ridicule? Curiosity is a hidden gift in most of us; we have it as little children, then we learn a few things and we bury the gift within us under a wretched, ill-selected bundle of facts which we think we know. The way to arouse curiosity is to stimulate it, and Prof. CLELAND proposes an excellent method. His remedy is:

"That every first-, second- and third-class postoffice be provided with a framed printed list of the federal and state publications which deal with the region in which it is situated, as well as of historical and other publications of local interest. . . . If it became generally known that every postoffice contained such a list of publications the traveler or resident in search of information would immediately go there to consult it."

The second suggestion is "that every postoffice have on sale all the federal and state publications on the exhibited list."

He then gives a delightful example of what might be displayed in his own bally of Williamstown, Mass. It includes topographic maps, a list of three works on local history with notes where the books may be consulted, a memorandum of the publications on the geology, the zoölogy, the botany and the agriculture of the region, with directions where the information may be obtained, and finally a list of collections and objects of local interest.

What an inspiration that would be! Instead of the natural resources of a district being discovered and recorded and then buried in archives and forgotten they would thus become subjects of public knowledge. The simple record of available information in a public place would stimulate industry and arouse minds that are caked to lethargy by the muddy sediment of dull, thoughtless days. Instead of sitting around the stove in the store discussing Judge DOGBERRY'S new teeth, or whose dog killed JOHN FERGUSON'S sheep, the neighbors would get a lead not only to talk but to think. It is the road to national enlightenment. The Scotch achieved merit by the discussion of free grace and foreordination, and made of themselves a race of thinkers. If we Americans discuss the resources of the home county we shall learn how to think too. We've been rather shy along that line since the war.

The Value of Short Reports

THE art of stenography, the recording dictagraph, and the typewriting machine are to blame for many troubles. It is a bother and a labor to write long-hand, and it is much easier to talk. And a great many of us do talk too much. The troublesome business of long-hand writing and the cost of printing a limited number of reports had the salutary effect in days gone by of inducing us to number our words. Nowadays the busy man gets too much to read. Newspapers are plastered over with useless "Bed Time Stories" and other mush, or news items carried over from a few inches of space on some other page, to provide that advertisements may be "next to reading matter." Nobody wants to learn how little Willie saved a robin's egg, and the inspiring fact that Cordonnier, Schuster & Shoemaker are having a great sale of boots and shoes, all at the same time.

The burden of complaint, however, is with the vast quantity of text that has to be read. Every professional man knows the task of keeping up with his profession, and we admit frankly that it is our business to add to this burden. His daily newspaper is almost a miracle of inconvenience, as far as an orderly presentation of the news of the day is concerned. His daily mail contains as many if not more circulars of tailors, automobile dealers, appeals, etc., which he throws away unread, than it does of actual communications which call for his attention.

The engineer or business man with his technical or trade paper has less to do than the professional man, but if he is a live wire he has still a great deal to read.

Then comes a report on something he wants to know. If he wants an exhaustive treatise he is likely to say so beforehand, but unless he calls for it he doesn't want it. If it is too long he gives a sigh and digs in for a few minutes, and then puts it into his basket of

unfinished business. He takes it home with him at night, and loses patience over having to wade through information that he does not want. Then the chances are that he will turn to the summary and reach his conclusions from that, being a little nettled over the fact that he did not get what he wanted earlier.

When he goes to his lawyer he is not charged for the length of the interview: it may last 15 minutes the first visit, the lawyer may work two weeks over the problem and then telephone the one word "Don't." But his counsel fee will not be nominal.

With no suggestion that reports of research of any kind shall be superficial, we make the plea for conciseness in technical reports whenever this is possible. All details should be duly annexed and speedily available, but the reports themselves should measure up to the novelist's rule: "First catch the reader, and then hold him."

Shuffling the Pack and Dealing a New Hand

PLAYING cards have been personified by the fortune teller ever since they came into vogue centuries ago. It may be stated without hesitation that cartomancy, which is the scientific name of fortune telling with cards, has had and continues to exert a far greater influence on human affairs than the oracles did in pre-Christian times. This was due to the fact that there was but one Delphian and one Dodona, each of which was no more productive of interpretation signs upon which to base plausible stories than a 32-card pack with sevens low. The card pack had distinct advantages over the oracle in that it was portable and was not limited as to number. It was in the manufacture of cards that the printer found the first great outlet for his craft, which was too crude in the early days to merit any monetary return on an art basis. In this contribution alone cards have had a stupendous influence on human affairs.

This is not the place to dwell on the phases of a subject which properly belongs to EDMOND HOYLE, so the rank of hearts and diamonds and the hundreds of other human points involved in cards will not be discussed. We only want to look at an ancient analogy from a new point of view and reverse on seeing humans in cards and see humans in terms of cards. We are already familiar with the Ace in this light, thanks to our aviator friends. During the past year we have witnessed the greatest human shuffle and redeal in the personnel of our industrial companies that has ever been known. We have seen some companies exchange their old cards for better ones and improve their hand. Others have lost very seriously. Some have gambled rather recklessly and let luck take its course.

Satisfaction with any hand all depends whether poker, euchre, whist or bridge is going to be the game in which the hand is to be played. Right and left bowers may top the aces in euchre. A straight flush made up of humble number cards is a hard hand to beat in poker. The idea in general that a hand must be all aces to be high is a false one in personnel as well as in cards. A proper conception of this fact is of vital importance to those concerned with personnel. Men are not labeled with simply read marks like cards and here lies one of the greatest difficulties. Character analysis may and may not be as exact a science as is being openly and publicly claimed at the present time. There is no

doubt that some executives are endowed with extraordinary faculties of sizing up men. There are many individuals, however, who are mere quack practitioners. Recently one of the latter variety was called in to reorganize the personnel of a firm, and going up the elevator, he observed that the elevator operator showed financial characteristics. In the course of his examinations, he found the cashier of this firm had mechanical tendencies. So he had the jobs of the two changed. The result was that the following day both cash and new cashier had disappeared. The elevator boy had lifted the cash. And so the human shuffle goes.

Authoritative Opinion On Synthetic Food

A FEW days ago Mr. Ford told a reporter of the *New York Tribune* that the gentle cow is doomed to follow into oblivion that expensive hay motor known as the horse. The chemist, it seems, is about to synthesize milk and cream from grain. We are glad to have the particulars because we might have guessed he would do it from acetylene and air and ammonia. Commenting on Mr. FORD's assertion, however, a chemist attached to the New York State Dairy Commission declared that the motor manufacturer was in error and that the cow is likely to be with us for some time. Mr. FORD's opinion on synthetic milk took him far afield from the subject about which he knows most and is best qualified to express an opinion.

Chemists, however, are addressing themselves to the important and pertinent subject of human food, as indicated in recent articles in this magazine by Dr. ALSBERG and Mr. HILTNER. Referring to synthetic food, the latter went so far as to say: "The kitchen is not the normal place for the chemist. The trained appetite will not willingly open its mouth for chemical food. The layman in his mind associates chemicals with poisonous acids and vile smells and wants none of them for food. 'God-made' foods are to be preferred to 'man-made.'"

We are not certain about any of these opinions, expert or inexpert. We have no idea how we should feel or what we should think if we had as many millions as Mr. FORD. Probably it would make us didactic also. If we had the conviction that milk and cream might be synthesized from grain, we should probably instigate research in the matter. Cows are a nuisance, and they are subject to all sorts of disorders. The Dairy Commission chemist is evidently interested in his job, and he is for permanent cows. It seems to us, however, as though some new kind of disease might carry off so many cattle that we should have to find sustenance and comfort (until the days of synthetic milk, if these come) in the more hardy goat. We have had many tender spots from and for goats; and we attribute the experience to the fact that goats are like some men we know in habit, manner and mind.

We lack also Mr. HILTNER's catholicity; we are not in agreement about all of the "God-made" foods, although, like him, we desire to please the canners because they have sense and engage in research with intelligence and understanding. It seems almost profane to call some natural foods "God-made." And we differ vigorously about the place of the chemist in the kitchen. The kitchen needs the chemist on the ground of economy, and the chemist needs the kitchen to give him a basis of art—the great art of cooking. In the

glorious days of Kingdom Come we expect to see, provided we are equipped with the ghostly eye, the kitchen of every chemist in his dining room and apart from the scullery. The chemist will cook his own dinners, and of all the men in town he will be the one most diligently sought after for his company. The girl that marries the chemist will be in luck, for then she can snub her dearest enemy by not inviting her to dinner. The London aldermen with their turtle soup and their turbot will suffer pangs of jealousy unless they can induce some distinguished chemist to volunteer to cook for them on Lord Mayor's Day. When the chemist enters the kitchen door he will find it *open sesame* to any class of society he desires. We know a chemist who cooks his own dinners, and so far as we are aware he is the most popular man in his home town.

Special Experts:

Charwomen and Chemists

IN A long article in the New York *Herald* of Feb. 27 on the 100,000 jobs, more or less, to be filled by President HARDING, there is a note to make chemists blush.

It states that "Government jobs are divided into four general classes: Those filled by the President with Senatorial approval, those filled by the President and one of the executive officials without Senatorial approval, those within the civil service list, and those carried on the rolls because of special fitness for the work to which they are assigned but without regard to the civil service—for example, certain groups of chemists and special experts and charwomen and laborers."

It sounds almost Russian; modern Russian. We heard the other day of a gentleman of Moscow who had formerly held a post of great dignity and requiring special training and fitness. He now serves the Soviet State in a post that requires his special training and fitness but, of course, without the dignity. A place to live is assigned to him and his wife. Early in the morning he goes out, chops wood, brings it in and builds a fire, and his wife, who is delicate, cooks his breakfast. Rations are assigned to him which he brings home after the day's work. Servants are not. They are not allowed. The proletariat rules and it does not serve. Then the old gentleman gets theater tickets as often as it is right and proper for him to be amused. There is no buying or selling or even trading. The Soviet State provides what it holds to be good for everyone.

If this were a Soviet government, of course the priority in the *Herald's* list would have been changed. It would have dealt with charwomen and chemists instead of the other way about. That would provide alphabetical sequence too, and it is possible and even likely that the charwomen outrank the chemists in point of age and length of service.

The whole thing is democratic, but we might as well fess up and tell the world that when it comes to training and fitness we think people are different and that they do not grade alike. Between mopping up a floor and the manipulation of delicate apparatus with the necessary thought as to what such apparatus shall do, we think we can see a difference. We do not like the word physicist; we agree with the late Lord KELVIN that the only real physicist is a siphon of soda water. But we haven't a better word at hand to indicate the men who should be classed with chemists rather than charwomen, and perhaps physicists are, in the eyes of government, "special experts."

Successful Chemical

Research in Anæsthesia

IN A paper recently presented before the American Oil Chemists Society, Dr. CHARLES BASKERVILLE, head of the department of chemistry of the College of the City of New York, pointed out a new use for edible oils in surgery.

It is well known that the vapors of ether or chloroform, when inhaled, produce the condition known as anæsthesia. This action is contingent upon the drug being taken up by the blood through the capillaries of the lungs. Exclusion of air produces asphyxiation, so that care must be observed to employ the proper mixture of ether with air to provide muscular relaxation and unconsciousness to pain—but no more. The process is a severe tax upon the patient, it chokes him and afterward nauseates him, and he dreads it.

The circulation of the blood takes place through numerous channels around the intestines, the stomach, indeed the whole alimentary tract as well as in the lungs, and numerous unsuccessful efforts have been made to administer ether or chloroform in the lower bowel by means of an enema. But ether boils at 34.6 deg., while the normal body temperature is 37. The lungs proceed to exhale ether almost immediately, but the dose is taken too fast and the subject may be asphyxiated. Little progress was made until Dr. J. T. GWATHMEY of New York conceived the idea of using the solubility of ether in oils and administering such a solution as an enema. Dr. BASKERVILLE has been working in collaboration with Dr. GWATHMEY for several years, and the result is a series of oil-ether solutions with the rates of evaporations determined and controlled. Various vegetable and mineral oils are used. After many experiments with animals the method of oil-ether enema was applied to persons and the result is a record of nearly 30,000 operations every one of which was successful from the patient's point of view. A short time after the enema is begun, ether is evolved from the patient's breath, but usually before he is aware of the odor of the anæsthetic, a gentle sleep has intervened.

Since an enema is often administered before an operation, there is no occasion to tell him that it is imminent. There is no occasion to tell him even which enema is made with the oil-ether solution, and thus the whole horrible dread of the thing is avoided. When the patient awakes there is no nausea, no retching; he is all bandaged, and the surgical business is finished.

In the army abroad when wounds of soldiers had to be re-dressed at the front and base hospitals, the men suffered tortures. Dr. GWATHMEY harked back to his investigations with Dr. BASKERVILLE on oil-ether colonic anæsthesia. He was reminded also of the rapid-fire action of ether when taken as an intoxicant in Ireland and by "Piccadilly Willies" in London. So he prepared an "oil-ether cocktail" in which the British army surgeons joined him. "The initial auto-human experiment," says Dr. BASKERVILLE, "was a success." Two thousand wounded soldiers after that were given such "cocktails" prior to dressing their serious wounds. The soldiers enjoyed the first exhilaration, dropped asleep, and three hours later awoke refreshed and all unconscious that their wounds had been completely examined and re-dressed. Some of our own surgeons since returning have availed themselves of the method in civilian practice in dressings after operations.

Readers' Views and Comments

Who Is a Chemist?

To the Editor of Chemical & Metallurgical Engineering

SIR:—Any man who has been fortunate enough to receive chemical training and who has even martyred himself in the cause of science will not be so presumptuous as to boast that he is trained to meet a multiplicity of problems. That the real chemist differs from the craftsman in that his mind is trained to meet a multiplicity of problems is undoubtedly true if we properly interpret multiplicity. The word as it appears in the subject editorial seems rather broad and perhaps more inclusive than is desired or can be verified in the cold world of facts.

This age of specialization renders constant application to the study of one field imperative to the man who would attain success. The expert metallurgical chemist would find himself entirely incompetent to be consulted on a problem in sugar refining. A chemist proficient in the science of distilled liquors would find himself wandering aimlessly if confronted with a mountain of oil shale. Thus it seems that multiplicity is not the proper word. Perhaps its scope in the explanation should be restricted.

The task of educating the public in a chemical way and to such an extent that the service and necessity of chemistry will be appreciated involves something besides the certification and legalization of the profession. Perhaps the chemical ignorance of the public is due to reluctance on the part of the men who are competent to come forward with an educational program. The fact is that the men who have given their lives to the pursuit of the subject are not prone to proclaim their proficiency from the housetops.

Lawyers and doctors are legalized, and rightly so. Are we to believe that the public has become aware of the necessity and service of the lawyer because of the legalization of the profession? The people caused the legalization of the profession by demanding protection from professional quacks. The people realize the danger underlying the employment of incompetents. The danger incident to the practices of unscrupulous "chemical experts" is not appreciated because the public has not the knowledge necessary to differentiate between their "merits" and demerits.

It has been through legislation arising from the demand of the people for protection that we know "who is a lawyer." The question "Who is a chemist?" will not be satisfactorily answered until the public realizes the need for a new protection.

Worcester, Mass.

G. C. MCCORMICK.

To the Editor of Chemical & Metallurgical Engineering

SIR:—Some time ago you asked this question in an editorial, and stated that it has not been answered yet. May I submit my suggestion as to this most important matter?

Chemistry today, both as a pure science and in its practical application, has come to the front in everyday life, in national development as well as in the welfare of mankind in general, to such an extent that it forms the broad foundation on which every future progress

of civilization will rest. This pre-eminent position of the chemical art is, however, not yet recognized by the general public, and this goal can be reached only by systematically educating and training the youth during school life in the all-important fundamentals of chemistry. This requires introduction of a correspondingly reformed school curriculum in grammar and high schools, as I had already outlined eight years ago in a special treatise on this subject, which found due recognition by high authority.

In the meantime it is of greatest importance, in regard to the high level of the chemical profession having been reached today, to determine who is its true and able representative—i.e., who is a real chemist. The word "chemist" must involve first of all a broad fundamental knowledge and training in the pure science of chemistry, on which rests the higher art of its practical application and its eminent cultural influence. Any man or woman is a chemist who possesses such a professional education along the science of chemistry that he or she is able to understand and to follow up with sufficient knowledge and clear vision every progress and problem within the realm of the chemical profession, be it in pure science or in its practical applications.

From the viewpoint of this definition, a man who practices chemical analysis from a routine standpoint only, without deeper knowledge of the scientific fundamentals of his art of chemistry in general, may be called an analyst, or better still a chemical analyst, but not a chemist, not even an analytical chemist. The latter is a chemist in its broader and higher sense, who makes chemical analysis his specialty. A chemical engineer is not a chemist, but rather an engineer with some chemical knowledge. An engineering chemist is a chemist who has some knowledge of engineering work as applied in industry. An electrochemist is a chemist with sufficient knowledge in electricity. A metallurgist without a broad general scientific knowledge and training in chemistry is not a chemist—if so, he may be called a metallurgical chemist. In this way any chemist may become a specialist in some chemical branch line and express his position accordingly.

The main point is that not everybody is a chemist who practices chemistry in some way or other with more or less skill; he may be a chemical worker of some kind, but not a chemist. The word "chemist" must become an exclusive title of high standard and meaning, according to the growing influence of chemistry and its art in cultural, economic and social life.

As soon as the question "Who is a chemist?" is satisfactorily solved the next important task would be to create an "American Chemists' Institute," whose membership and purpose would differ from the American Chemical Society essentially in the following points:

1. Only recognized chemists are admitted as members.
2. The main purpose of the new institute should consist in recording every achieved progress as well as any prospective new problem in pure and applied chemistry, thereby becoming the guiding authority along research for every individual worker. Publishing annual symposiums on all respective subjects.
3. Through special publications and lectures giving instruction and information to the general public re-

garding the influence of chemistry's progress on home and public life.

4. Establishing a universal library embracing every branch of chemistry, as a center for reference work.

5. Exercising influence to bring chemistry into the forefront of school education as being of fundamental importance for both sexes, especially in regard to health, hygiene and efficiency, constituting a national problem of the first order.

There are, of course, several other tasks which could be included in such a new organization, which, however, may be easily fixed and worked out after the fundamental statutes are determined.

Plantation Rubber and the Testing of Rubber

To the Editor of Chemical & Metallurgical Engineering

SIR:—May I be permitted to comment on the review, in your issue of Jan. 5, of my book on rubber?

(1) Your reviewer's statement that I have "omitted all mention of the valuable papers on rubber which have appeared in CHEMICAL & METALLURGICAL ENGINEERING during the past five years" would seem to indicate that he has not read the book with much attention. In fact, mention is made of all such papers in which are reported original work bearing on the aspects of rubber discussed in the book, the paper by Kratz and Flower (CHEM. & MET. ENG., vol. 20, p. 417) being treated particularly fully. I may add that, so far from having failed to recognize the value of the papers on rubber which have appeared in CHEM. & MET., I have always found A. H. King's articles on various aspects of rubber technology to be of great interest and value.

(2) "The literature references," says Dr. Dannerth, "are for the most part English and Dutch, although one finds casual references to the work of Kratz, Flower, Tuttle and Cranor in the United States." The implication that I have paid a disproportionate amount of attention to the work on rubber, relevant to the aspects discussed, which has been performed in certain countries and have neglected that performed elsewhere, particularly in the United States, is, I venture to assert, not in accord with the facts. Your reviewer refers to the bibliography "in which the author has discovered [*sic*] 350 names of writers on rubber topics." Now an examination of these names shows that actually there are fewer names of English and Dutch than of French and German writers (approximately 130 and 170 respectively in the two groups). Further, nine pages in all are devoted to work published by Kratz; Tuttle's papers have been on matters of chemical analysis with which the book is not extensively concerned; Cranor's paper was published as late as December, 1919, when the book was in the press; and reference is made to an earlier-received private communication from Mr. Cranor. All other published work conducted in the United States which bears on the subjects treated, such as the work of Spence, Wormeley and the Bureau of Standards, is discussed fully.

(3) Dr. Dannerth's complaint that "all reference to synthetic rubber has been carefully deleted [*sic*] from the book" strike me as captious, not to say unreasonable, since the title of the volume, "Plantation Rubber and the Testing of Rubber," would, one imagines, hardly convey the expectation that synthetic rubber was within its scope.

(4) Your reviewer confesses that "a great deal of material on the physics and physical chemistry of rubber has in the volume been published in book form

for the first time," and yet he concludes that the book "will probably be of greater value to university men than to rubber manufacturers." Can it be that he fails to appreciate the importance for rubber technology of scientific investigations into the physics and physical chemistry of rubber? I would venture to commend to him an article on "Future Rubber Research" by A. H. King in CHEMICAL & METALLURGICAL ENGINEERING for Sept. 8, 1920, and the following excerpt, quoted in my book, from an editorial in CHEMICAL & METALLURGICAL ENGINEERING for June 15, 1919: "The rubber industry of today can learn a profitable lesson from a comparison of present conditions in the iron and steel industry with those of the 'good old days' before the spread of technical knowledge."

Ownership of Oil-Yielding Shales in New Brunswick

To the Editor of Chemical & Metallurgical Engineering

SIR:—The world-wide importance of an increased supply of hydrocarbon oils makes it very necessary that no person or group of persons shall be allowed, for the furtherance of their own plans and schemes, to make incorrect claims or statements, without the same being contradicted and their falsity made evident.

For some years a conspiracy would seem to have existed in a certain province of Canada, by which certain persons have endeavored to make capitalists believe that they or their friends owned or controlled all the oil-yielding shales of that province. These claims have to my knowledge been made in London, England, and in New York. Because of these claims being persisted in, especially in New York, I wrote as follows to the Hon. James Domville, a Senator of Canada, who resides in the Province of New Brunswick and who has an intimate knowledge of the affairs of that province, particularly as regards oil shales, of which he was one of the first New Brunswickers to recognize the importance. My letter was as follows:

DEAR SENATOR: Lately, when in New York, I was credibly informed that certain parties were claiming that they and their friends owned all the oil-yielding shale deposits in the Province of New Brunswick.

As I have the honor of representing owners of certain New Brunswick shale deposits, and as you are known to be largely interested in other New Brunswick shale deposits, I have considered it my duty to call your attention to this claim, the making of which has done and is doing grave injury to your province.

The Senator replied:

DEAR SIMPSON: I have to thank you for calling my attention to the claims you inform me are being made as to the ownership of the Province of New Brunswick oil-yielding shale deposits.

As you know, I have been interested for over ten years in the Albert mines, a shale property in this province. I have authorized no one to make any claim such as that mentioned by you.

This is not the first time that similar claims have been made by unauthorized or irresponsible parties. The Province of New Brunswick Legislature passed an act on March 26, 1910, entitled "An act to amend 'an act to incorporate the Albertite Oilite & Cannel Coal Co., Ltd.,' " being 1 Edward VII, Chapter 79, page 300. By this act, The New Brunswick Petroleum Co., Ltd, which in 1907 had been granted certain privileges, had those privileges curtailed, *vide* clause 1, which states, "Under the said lease to the New Brunswick Petroleum Co., Ltd., no interest in bituminous shales and Albertite was granted to said company."

I am, yours faithfully,

JAMES DOMVILLE.

In the interest of the nascent oil shale industry, may I ask you to make public this correspondence.

Ottawa, Canada.

LOUIS SIMPSON.

British Chemical Industry

From Our London Correspondent

LONDON, Feb. 15, 1921

AT THE time of writing, the tone of the chemical industry and of chemical markets is one of incipient optimism and cheerfulness and it is generally expected in well-informed circles that there will be a partial revival of trade and industry by June of this year. It is not considered that the removal of the excess profits duty will have any appreciable influence in this connection, the mischief due to its prolonged retention having already been discounted. Most factories are at present working only three or four days per week, the export trade is still very depressed, and in consequence prices are still slightly in favor of buyers. Considerable quantities of caustic potash are now arriving from Germany and, the demand being purely nominal, the market is overstocked.

Considerable friction and dissatisfaction have arisen on account of the peculiar attitude of the large chemical and dyestuffs organizations in regard to export trade. During the war, when supplies were strictly rationed, it was possible to acquiesce in the stipulation that the destination of the goods should be declared, but apparently the manufacturers, having now established their agents and distributing systems in foreign countries, are anxious to continue this inquisition for their own ends, and the result is a state of semi-revolt on the part of the merchants. In several cases recently the merchant has actually obtained the order for the goods from his foreign customer and was refused supplies by the manufacturer solely in order to protect the latter's agents. As a result, several important orders have been placed in Germany and elsewhere and were therefore lost to the home manufacturer on account of what is generally considered as a short-sighted policy. The attention of the government has been called to the situation.

PROGRESS IN DIRECT FUEL SAVING

The campaign for increased efficiency in the use of fuels has gradually spent itself and there is less activity in the installation of coal- and labor-saving devices for the boiler plants of the country. On the other hand, considerable attention has been given to the recovery of washed coke and breeze from industrial ashes and to the froth flotation of coal. A flotation plant to deal with about 1,000 tons per day of coking coal is to be erected at the Skinningrove Iron Works, on the northeast coast, the process used for metallurgical work being suitably modified under the auspices of Minerals Separation, Ltd. It is stated that about 1 lb. of reagent is required per ton of coal treated and that apart from the removal of dirt and ashes, considerable economies are to be expected on account of increased output of the coke-oven plant and improved quality of coke. The gas companies are vitally concerned in the success of the process, particularly on account of the very high percentage of dirt and stone sold to them by the mines along with the coal during the last few years. In view of the high freight rates which are still prevalent, it is expected that considerable net economies will result from the extended use of this process. On the other hand, the large quantity of inert products supplied with present-day industrial coal has greatly increased the carbon con-

tent of the ashes from boiler plant, which may be 10 to 20 per cent or more by weight. The Fuel Recovery Syndicate is now developing the Lioud process for treating ashes, the usual size of plant dealing with about ten tons per hour and the cost being about 10s. per ton of recovered washed coke or breeze. Two plants are already at work in this country and a large number in France.

PROPOSED FORMATION OF BRITISH ENGINEERS' CLUB

The example set by the Chemical Industry Club is apparently to be followed by the formation of a similar organization for engineers, and curiously enough the provisional committee also includes representatives of the chemical industry like Max Muspratt, Mr. Woolcock, M. P., and Sir Robert Hadfield. The general feeling is that a club of this kind will not prove a success at the present time unless the subscription is sufficiently low to bring it also within the reach of the younger members of the profession. The idea of a central home and club for all engineering societies has often been mooted, but could not come to fruition on account of the existing and very adequate buildings of the leading societies.

FINE CHEMICALS AND DYESTUFFS

The views outlined in my last article have been confirmed by an official statement just issued by the Association of British Chemical Manufacturers, which predicts the collapse of the industry unless a bill complementary to the dyestuffs act is passed. No final decision has as yet been reached in regard to the proposed key industries bill, but it is quite certain that heavy chemicals will not be included and fine chemicals will probably be restricted mainly to pharmaceutical products. On the other hand, there seems to be so much opposition and uncertainty that it is by no means impossible that the fine chemical industry will be left to work out its own salvation.

CHEMICAL PUBLICATIONS AND GENERAL NOTES

Considerable discussion and some amusement has resulted from the proposals submitted by the Federal Council for Pure and Applied Chemistry for the publication of chemical literature. To some extent the suggestions made follow the lines of the corresponding American journals, but it is suggested that the various societies should establish a joint weekly journal practically on the same lines as CHEMICAL & METALLURGICAL ENGINEERING. It is refreshing to notice the intense keenness which is being displayed in regard to the value of such a journal as regards advertising revenue, but it is felt that until the societies concerned can make up their minds to abandon control by committees in favor of sound and commercial journalism, a weekly journal of this kind will meet with little support, particularly as the public is already well served by several trade papers. There is also the fear that advertising revenue will seriously diminish in the near future, partly on account of the removal of the excess profits duty and partly on account of industrial depression.

The first volume of the new edition of Thorpe's Dictionary of Applied Chemistry has just appeared and is to be followed by six or seven additional volumes to complete the series.

The Kelvin gold medal has been awarded to Dr. W. C. Unwin, F.R.S.

American Ceramic Society, Annual Meeting

Assembled at the Birthplace of the Society, the Members Hold Scientific Fest — Papers Show Need for Enlarged Technical Control of Processes and Widened Scope of Industrial Activity—
Results of Original Research Made Public—Abstracts of Papers

THE twenty-third annual meeting of the American Ceramic Society was held at the Deshler Hotel, Columbus, Ohio, Feb. 21 to 24. Significant in its location, near the largest ceramic industries of America, inspired by the presence of Edward Orton, Jr., dean of American ceramists and virtually the father of the society, who was surrounded by many distinguished senior ceramists, the meeting held far more than the usual amount of spirit and morale manifest on like occasions.

The society is one where every member is the other fellow's friend. The smoker on Monday night and the informal dance and banquet on Tuesday evening were more like functions of an intimate social organization than perfunctory affairs of the national technical society. The emotions of the banquet assembly were varied from laughter at W. D. Gates' description of sweaters for keeping interurban engines warm to tears at the touching tribute paid to Ernest Mayer by Toastmaster Orton. The special entertainment for the ladies and the visits to industrial plants in the vicinity displayed hard work and good judgment on the part of the local committee. The visit to Edward Orton's cone factory, the Bureau of Mines ceramic station and the university was like a pilgrimage to an old shrine.

With old traditions of art commingled with ideals for the science and industry of the future, it is little wonder that the meeting was a success for every member and division.

Business Meetings

Officers elected for 1921 were as follows: F. K. Pence, president; F. B. Ortman, vice-president; R. K. Hirsh, treasurer; R. M. Howe, trustee; E. W. Washburn, editor of the *Journal*.

The glass division has been invited to tour industries in England by the English society. The executive committee is considering the appointment of a full-time secretary. Arrangements are made for preparing abstracts of ceramic literature in co-operation with the American Chemical Society.

The American Ceramic Society has voted to join the Federated American Engineering Societies, if financial arrangements can be made.

Edward Orton made an eloquent plea that proper steps be taken to perpetuate the name of Ernest Mayer by suitable memorial, and a committee of five was appointed to work out details.

PRESIDENTIAL ADDRESS

R. H. Minton's presidential address on "Some Problems to Be Solved" revealed a masterful grasp of the situation existing in the ceramic industries today and was referred to a special committee for careful analysis and disposition in the form of instructions to the divisions of the society. It is abstracted in part in the following paragraphs:

With oxygen, silica and alumina forming 85 per cent by weight of the elements of the earth, we can conceive the magnitude of the foundations of our work. Secret methods are no barrier to technical competition. The future problems are chemical and physical on one hand and mechanical and human on the other. Scientists must solve our general problems, involving fundamental laws affecting drying and firing, heat transmission and heat losses, problems of combustion and kiln construction, kinds of fuel and control of processes.

The glass manufacturer needs knowledge of chemical reactions and physics of heat-treatment. Silica brick, quartz glass and porcelain industries need technical advice. Research into the chemical composition and properties of glazes is needed. More must be learned of the relation between glazes and frits and the solubilities of lead glazes. Specifications are needed for refractories.

Other problems are the disintegration of clay products by weathering, the dunting of sanitary and terra cotta bodies, the failure of refractories under load and the improvement of electrical porcelains. Plasticity of clays is also a most important subject. The mechanical and organization problems are vital engineering subjects. Standardization of methods and products is badly needed.

Research and development in many lines must come. For our purposes chemistry and physics are the most important. We must co-operate with and support government bureaus. Economic co-operation in market development, both foreign and domestic, must come. We should solve the employment situation. It is the function of the American Ceramic Society to promote all these interests in the clay industries.

Enamels Division

FISH SCALING

The Causes and Control of Fish Scaling of Sheet Steel Enamels, by R. R. Danielson and W. H. Souder. The U. S. Bureau of Standards conducted an extended investigation with simple gray ware enamels and commercial formulas. These were applied to 20-gage steel and the effects noted on variations in firing, thermal expansion of enamels, annealing composition of steel and mechanical treatment of steel.

The fundamental cause of fish scaling lies in the difference of coefficients of expansion of enamels and steel, that for steel being higher than for enamels, so that the latter is under compressive strain. The factors influencing this phenomenon are composition of enamel, overfiring, with consequent volatilization of part of contents, and lack of annealing the enameled ware, which is glass and must be so treated. Secondarily, fish scaling is influenced by the physical condition of the metal, elastic strength of the glass, underfiring and cleanliness of metal surface.

It may be remedied by adjusting the enamel coefficient

of expansion to fit that of steel—i.e., by decreasing its boric acid content; by changing composition to increase strength, and by treatment of metal to give best adhesion, as by cold-rolling, etc., and correct preparation of ware in cleaning process. This paper was accompanied by numerous charts and curves to substantiate the findings.

John S. Grainer followed with a plea for further scientific investigation and increased technical control of the industry, reviewing conditions where secrecy and unwillingness to co-operate on the part of the practical enameler have stifled progress. He attributed fish scaling to overfiring, poor composition and poor furnace construction and spoke highly of the excellent work done by the Bureau of Standards. An explanation of fish scaling was also undertaken by J. F. Bardbush, and the three papers are a distinct addition to the literature.

COPPER ENAMELS

Copper enamels were covered in two papers. A preliminary report of work being carried on by B. T. Sweely stated that with an arsenic content of 0.1 equivalent As_2O_3 in an enamel of one type applied by the dry method the following relations held true: (1) Increase of silica with RO , arsenic and boric constant, increases tendency to fracture, increases refractoriness and does not affect opacity and luster. (2) Increase of boric acid above 0.2 equivalent causes enamels to matt. (3) Increase of K_2O at expense of PbO causes enamels to flow better and to mature at lower temperature, increases solubility and decreases tendency to fracture. (4) High-lead enamels are opaque, but do not flow well and attack the copper.

The following limits were recommended:

$$\left. \begin{array}{l} 0.3-0.6 \text{ KNaO} \\ 0.7-0.4 \text{ PbO} \end{array} \right\} \begin{array}{l} 0.05-0.15 \text{ As}_2\text{O}_3 \\ 0-0.2 \text{ B}_2\text{O}_3 \\ 1.3-1.8 \text{ SiO}_2 \end{array}$$

R. R. Danielson followed with an outline of his investigations on twenty white enamels for copper. While the number of investigations was small, he offered the following results: (1) Correct smelting is extremely important, slow air cooling of frit is preferable to water quenching and repeated smelts promote opacity and eliminate gas. (2) Certain reducing atmosphere in the furnace eliminates copper oxidation. (3) Slight changes in composition have a decided effect on resultant properties. (4) Sodium oxide promotes glass but reduces opacity. (5) Lead oxide promotes fusibility without materially reducing opacity. (6) Cryolite is not desirable, as it tends to promote matt finish. (7) Keep B_2O_3 content low. (8) Arsenic is an excellent substitute for tin oxide.

Two of the formulas showed best for watch dials and three others for thermometer scales, sign letters, etc.

SOLUBILITY OF ENAMELS IN ACIDS

Solubility of enamels in acids as related to the composition was discussed in an exhaustive paper by Homer F. Staley. The question is important in the manufacture of chemical ware used in the many industries. The various materials affect the acid resistance in the following order, the most advantageous being named first: Al_2O_3 , cryolite, Na_2O , PbO , BaO , Li_2O , MgO , CaF_2 , ZnO , SrO , CaO and B_2O_3 .

When substituted one for another in equal percentage amounts, various oxides and minerals affected the resistance of enamels to the action of boiling 20 per cent hydrochloric acid in the following order, the most

favorable being named first: Al_2O_3 , MgO , CaF_2 , ZnO , SrO , CaO and B_2O_3 . The first five are especially desirable, while the remainder are undesirable. The relative effect of the materials used in the experiments was the same with various base enamel compositions. When substituted one for another ZrO_2 , TiO_2 and SiO_2 affected the resistance in the order named. The favorable action on acid resistance conferred by ZrO_2 is offset by a tendency to produce excessive chipping. Rutile gives less chipping than either zirconia or silica and greater acid resistance than silica.

WET PROCESS ENAMELS FOR CAST IRON

R. R. Danielson gave the results of preliminary work at the Bureau of Standards in developing wet process enamels for cast iron. This information was of particular value to many manufacturers, especially producers of stove parts. The subject hinges on the development of a suitable ground coat. Refractory ground coat showed greater freedom from pinholing. A medium amount of raw material in mill additions is desirable, since high contents give rise to flaking and small amounts give rise to pinholing in the cover enamel. Clay is a better mill addition than flint or feldspar. The composition of the frit portion is more important than mill additions. Dry process ground coats are not necessarily suitable for the wet process. It is desirable to continue the study of this subject.

FIRING ENAMELS

A. Malinovsky's paper dealt with the melting of enamels in rotary furnaces as compared with the ordinary reverberatory type, the former showing more uniform product, freedom from contamination by rabble irons and furnace linings, lower losses through adhesion to walls and lower fuel consumption. He described the construction and operation of a U. S. Smelting Furnace Co. furnace with lantern slides.

L. E. Barringer gave a treatise on the application of electric heat to vitreous enameling, with particular reference to the furnace developed by the General Electric Co. This most recent addition to the art is attracting considerable attention in the enameling industries.

B. T. Sweely gave notes on the acid resistance of enameled cooking utensils as affected by the position of firing. The under surfaces of pieces as placed in the ovens are more resistant to citric and acetic acids than the upper sides. The inner surfaces of enameled vessels may be made more resistant to acids of the kitchen by firing in an inverted position.

Refractories Division

MOLDS FOR MAGNESITE, CHROME AND SILICA BRICK

Erling E. Ayars described at length the best types of molds for making magnesite, chrome and silica brick. Slip molds are used for silica brick. Chrome and magnesite brick are made largely by machinery and a machine is now being developed for pressing out silica straights. Special shapes will eventually be eliminated from coke-oven construction and only 9 in. straights employed.

TESTING COKE-OVEN REFRACTORIES

F. A. Harvey offered a complete report on the methods of testing coke-oven refractories together with specifications for them. The paper was the result of several years' intensive work on the subject in con-

nection with the ovens of the Semet-Solvay Co. The proper testing of refractory materials requires a clear understanding of conditions both ordinary and extraordinary which the materials must meet in service. The tests must then be made for size, warpage, ring, load and vitrification; reheating to 1,450, 1,350 or 1,200 deg. C. as required; fusion point; bulk density, apparent density, true density and porosity; bending and load; crushing and modulus of rupture, spalling, fineness, plasticity and heat conductivity.

All silica brick and shapes must pass the 1,200 deg. C. reheating test and show not more than 1.6 per cent average permanent linear expansion. For regenerator checks up to 2 per cent can be allowed. Lime content should not be specified until more complete data on the effect of lime are available. Alumina should not exceed 1.65 per cent. For fineness of grind 97 per cent of material should pass a $\frac{1}{4}$ -in. mesh screen. All class 1 silica brick should have a modulus of rupture of not less than 500 lb. and a cold crushing strength of not less than 1,600 lb. per sq.in. Class 2 silica brick should have a modulus of rupture of not less than 350 lb. and cold crushing strength of not less than 800 lb. per sq.in. Class 1 brick should be used in bench walls, corbels and oven linings. Shapes should not have a variation in dimensions greater than $\frac{1}{16}$ in. per ft. for brick under 12 in. and $\frac{1}{8}$ in. per ft. for larger pieces. Visual inspection and hammer tests should eliminate cracked and badly warped pieces.

Clay brick in the reheating tests should not show a swelling greater than 1 per cent nor a shrinkage greater than 1.6 per cent. Bending tests should not show greater than $\frac{3}{8}$ in. for 1,450 deg. C. heat and $\frac{1}{4}$ in. for 1,350 and 1,200 deg. C. heats. Dimensions should not vary more than $\frac{1}{8}$ in. for standard sizes under 12 in. nor more than $\frac{1}{16}$ in. per ft. for sizes over 12 in. Statement must be made as to whether brick is hand or machine made.

Silica cement must have fusion point as high as cone 27, must all pass 30-mesh screen and must survive the pail test. It must contain not over 25 per cent plastic clay.

Fireclay ("A" quality) should spread easily and smoothly with trowel, pass 14-mesh and 95 per cent pass a 20-mesh screen, and fuse not lower than cone 28. "B" quality may fuse as low as cone 20.

ZIRCONIA CEMENTS

Mark Sheppard's paper on zirconia cements brought out the fact that crude zirconia with high shrinkage and impurities could not be bonded with clay to make a satisfactory cement. When a part of the crude zirconia, however, was partly replaced by pure zirconia, the purified material having lower shrinkage, a cement could be formed. When this was applied as a wet wash to a bung on malleable furnaces, an increase of 25 per cent was secured in the number of heats run before replacement.

HEAT-TREATMENT OF SILICA BRICK IN THE CROWN OF A TUNNEL KILN

A. A. Klein in discussing the heat-treatment of a silica brick in the crown of a tunnel kiln stated that after the heating it contained no quartzite, low amount of tridymite and nearly 100 per cent cristoballite where the previous composition had been equal parts of each.

This is evidence that all quartzite tends to change over to cristoballite on heating.

J. W. Hepplewhite proposed a departure in the method of measuring actual thermal conductivity of refractories by bringing both sides of brick to a high temperature and measuring the heated air delivered from a chamber on the cooler side. Some discussion followed his description of the apparatus and suggestions were made as to methods of overcoming difficulties encountered in performance.

W. Henry Grant has found little information available as to the major cause of failure of firebrick in oil-burning furnaces. The brick do not burn but disintegrate. A dense fine grind made into hard-burned firebrick has been found to give best service.

R. M. Howe in tests conducted at the Mellon Institute with a flint clay firebrick in which the plastic clay bond was kept constant and various amounts of gannister were added, displacing the flint clay, found that the addition of gannister increased the resistance to spalling at intermediate temperatures. At higher temperatures no advantage was discovered and at the lower limiting temperature for firebrick a disadvantage was encountered in the tendency to lower the melting point as the mix approached the eutectic for alumina and silica.

Glass Division

TRAINING OF THE GLASSWORKS CHEMIST

Alexander Silverman outlined a suggested college course for the training of the glassworks chemist, with a first year course to include general inorganic chemistry, mathematics, English, German and some general work in the factory. Second year should include advanced inorganic chemistry, advanced physics, mathematics, German or French, quantitative and qualitative analysis and factory work. The third year should embrace physical chemistry, quantitative analysis, mineralogy, pyrometry, microscopy, organic chemistry and laboratory work in the factory. The final year's work should include clays and refractories, glass technology, ceramic calculations, engineering laboratory, electrical engineering and factory management.

Some think the glass chemist is so specialized there is no need for him in the industry, but the training suggested coupled with practical experience will develop a man to become an important factor in industrial development.

COMPOSITION OF BARIUM GLASS

R. J. Montgomery gave the result of research in the composition of optical glasses whose properties are dominated by the barium oxide content. The batch is more complex than that of lead glasses, which have a three-component system of alkali, lead and silica, while barium glasses have a second acid (B_2O_3) introduced together with Al_2O_3 as well as more complicated RO, containing zinc and calcium in addition to alkali and barium.

There are no simple relations between composition and optical properties, and the relations as observed in the charts must be expressed in the most general terms. Deductions were made on BaO versus optical properties, B_2O_3 and SiO_2 versus optical properties, SiO_2 versus BaO and SiO_2 versus alkali. The proportioning of the RO bases, the Al_2O_3 , ZnO and alkali contents was discussed. Each particular glass is a problem in itself and the details cannot be covered in a general paper.

DISSOLVED GASES IN GLASS

E. W. Washburn gave an exhaustive report of investigation of dissolved gases in glass, which in addition to appearing in the *Journal* of the American Ceramic Society will shortly be issued as Bulletin 118 (1921) by the University of Illinois Engineering Experiment Station. The work was begun in 1917 and is just completed. The results to date lead to the conclusion that all varieties of glass in the finished state contain dissolved gases. The amount of this dissolved gas is sufficient to cause the glass to effervesce violently if the pressure upon it be suddenly reduced while in a fluid condition. The amount and composition of the dissolved gas varies greatly with the type of glass and the detail of the melting and fining procedures. In three types of industrial glass examined, the volume of the dissolved gases, measured under standard conditions, varied from 0.2 to two times the volume of the glass itself. Carbon dioxide, oxygen and nitrogen were found in various amounts in the gas.

THE OPERATION OF LEERS

C. E. Frazier spoke on the essentials of proper annealing of glass articles from a practical standpoint. The factors involved are the shape, weight, temperature at which the glass is worked and whether the article is blown or machine made. The strains created in the latter will be proportional to the difference in temperature between the plunger mold and the glass. The annealing temperature varies from 800 to 1,100 deg. F. and the time from 45 min. to 1 hr. 20 min. Proper annealing involves correct mold design, working temperature, temperature annealing chamber, soaking time and a gradual cooling on removal from annealing chamber. Comparisons were made of the open, muffled and continuous leer.

Heavy Clay Products

This division was organized with Ross C. Purdy chairman. The scope of activity will include common brick, drain tile, facebrick, sewer tile and other fields involving the heavier ceramic industries. The discussion centered on the co-operative movement with the various national associations of these products. A. V. Bleininger reported the work as carried out by the ceramic committee of the National Research Council. The hollow tile producers are also inclined to join. Joint conferences have been held by the executive committees of all these associations and all approved the plan for each association to appropriate \$10,000 a year for two years to establish a fund for research and have recommended it back for approval by each association. The formation of this division for the work will greatly increase the American Ceramic Society's membership.

The Art Division

Under the chairmanship of Frederick H. Rhead of Zanesville, Ohio, the new division giving art a definite place in the society was formed. The following papers were presented at the close of the business session:

"The Mutual Relations of Art and Technology in the Ceramic Industry," Leon V. Solon, New York City; "Relationship of the Artist to the Manufacturer," Conrad Dressler, Cleveland, Ohio; "Some Suggestions for Research in Commercial Decorative Processes," Frederick H. Rhead, Zanesville, Ohio; "Ability of Variable Glaze Compositions to Take Vapor Lustres,"

Ray T. Watkins, Columbus, Ohio; "Nickel Oxide in Glazes," J. D. Whitmer, Zanesville, Ohio; "A Study of Crystalline Glazes," Hobart N. Kraner, Columbus, Ohio.

Kilns

As in previous years, the general session included a symposium on kilns directed by R. H. Minton, which was attended by members from all branches of the society.

DATA ON A DRESSLER KILN

F. H. Riddle gave some real data on a Dressler kiln which had been in operation seven months at cone 18. The condition of the structure at the end of the period was classed as a temporary delay and not a failure. Many have been skeptical about the success of tunnel kilns above cone 11. Cone 20 has been reached in the case at hand. The structure is 300 ft. long with silica brick arch in the hot zone (40 ft. long) and the remainder firebrick. Photographs showed the rise in this arch due to greatest heat, 2,678 deg. F., was 1 $\frac{3}{4}$ in. The flue boxes were replaced with carborundum brick. The mortar stood up well, but reacted with the carborundum to break the latter down. Where no binders were used the carborundum stood up well.

Examination of the silica brick in the hot zone (2,400 deg. F.) showed that the edges next to the heat were completely converted to tridymite and the outside edges crystoballite. There was no difference in expansion between the two parts of the brick. Electric porcelain can be burned in the tunnel kiln.

DESCRIPTION OF A UNIQUE KILN

C. B. Harrop spoke on the construction of two of his kilns installed at the Mt. Clemens Pottery Co., Mt. Clemens, Mich. The installation was unique in that two kilns were placed end to end for bisque and glaze burning. The former is 325 ft. long operating at cone 10 and the latter 273 ft. long at cone 5. They are burning white ware in this open-fired, hand-stoked type. The ashes are automatically removed. The firebox has an enlarged throat and the walls of the main chamber are sloped in at the top to produce even distribution of heat.

The coal burned is Elkhorn Kentucky grade and burns one dozen bisque for every 1.22 lb., against 7.8 lb. consumed in periodic kilns.

COMPARTMENT KILN FOR CLAY PRODUCTS

W. D. Richardson gave a paper on the adaptability of the compartment kiln for clay products. Attention to fuel saving is becoming important. The tunnel kiln has been the dream of potters for a long time. In the old experiments with this type it was found that the only installations that could not be inspected were those that failed. The latest compartment kiln development can be adapted to any type of ware where gas is employed for heating. No saggers are required to protect ware. It saves from 50 to 60 per cent of fuel over the periodic kiln, is compact and adaptable to plant conditions, requires no ash handling, has better burn control, uniform product, low repair costs, and a wider range of practical utility than any other type.

THE SHAW COMPARTMENT KILN

R. H. Minton spoke on the Shaw compartment kiln, stating that these are used widely in England, while the tunnel kiln is popular in Germany. The former compares favorably with the tunnel kilns for fuel economy and is more adaptable to existing plants.

Investigations of the Chemical Literature—I

A Survey of the Field of Chemical Literature and of the Various Kinds of Searches or Investigations—Library Research—Use of Card Index Catalogs, Shelf Lists and General Reference Works*

By FRANK E. BARROWS†

THE chemical literature is the storehouse of the available published information of chemical science and chemical industry. It is most extensive, both in the wide range of subjects which it includes and in the long period of time over which it extends. Investigations of this literature are often required. Proper investigation requires a familiarity on the part of the investigator with the various sources of information and with the facilities available for using them. The importance of proper training and guidance in making investigations of the chemical literature is not as generally recognized as it should be.

The present paper is a contribution to the general subject of the chemical literature and its investigation, and includes a discussion of the use of library facilities and general reference works, and of the searching of the periodical and other literature.

The Field of Chemical Literature

PERIODICALS

The number of current periodicals systematically examined for *Chemical Abstracts*, according to the list published in 1918, was 789. Bolton, in his "Select Bibliography of Chemistry," published in 1893, lists 436 periodicals, while in his "Catalogue of Scientific and Technical Periodicals, 1665-1895," published in 1897, he gives the following numbers of periodicals as relating to certain branches of chemistry: General chemistry, 154; pharmaceutical chemistry, 30; physiological chemistry, 6; technical chemistry, 94; dyeing and printing, 21; illuminating gas, 30; iron industry, 33; ceramics and glass, 32; metallurgy, 44; mining, 165; oils, fats, soap, etc., 22; sugar, 43; tanning and leather, 11; wines and spirits, 48. Even as early as 1848 Gmelin, in vol. 1 of his "Hand-Book of Chemistry," gives a list of 77 chemical periodicals of earlier date.

OTHER LITERATURE

In addition to the periodical literature the field of chemical literature also includes the patent literature, the text book literature, and the numerous histories, hand-books, dictionaries, encyclopædias, technologies, pamphlets, bulletins, monographs, dissertations, public documents, trade catalogs, reviews, indexes, bibliographies and other books and publications which relate, in whole or in part, to chemical science or to chemical industry.

VARIOUS FIELDS OF CHEMISTRY

In the general field of the chemical literature are numerous branches or subdivisions, including:

Agricultural chemistry, analytical chemistry, apparatus, biochemistry, ceramics, cement, colloidal chemistry,

dyestuffs and dyeing, electrochemistry, explosives, fermentation, fertilizers, foods, fuels, gas manufacture, glass manufacture, general inorganic chemistry, leather, metallurgy, mineralogical chemistry, oils and fats, general organic chemistry, paints and varnishes, paper making, perfumes, petroleum oils, pharmaceutical and medical chemistry, photography, physical chemistry, plastics, resins, rubber, sanitation, soap, sugar, textiles, theoretical chemistry, water, and wood distillation.

This list might be elaborated or abbreviated, depending upon the particular standpoint from which the field is considered.

Some of the chemical periodicals are of a general character and embrace many of these branches; others relate to certain branches only. The chemical literature, other than the periodical literature, is likewise in part of a general character and in part specialized and limited to certain subjects or branches.

It is apparent that the chemical literature is of a most extensive character, both in the wide range of subjects which it includes and the long period of time over which it extends.

Various Kinds of Searches or Investigations

Searches or investigations of the chemical literature, of a more or less comprehensive character, may be made from various standpoints—e.g., by the research chemist, to familiarize himself with the available published information along the lines of his research; by the student, as a part of his studies or research; by the writer or author who, in his articles or publications, desires to give credit to the work of others, or to review the prior literature along the lines of his own publication; by the bibliographer, as the basis of his bibliography; by the manufacturer, to obtain information of interest along the lines of his manufacture or along new lines of development; by the patent investigator, in connection with questions relating to the novelty and patentability of inventions, and the validity and infringement of patents, etc.

It will be evident that the character and scope of the search or investigation will vary, depending upon the particular object the searcher has in view.

The value of any search or investigation of a comprehensive character will depend on its thoroughness and completeness, and this will in turn depend upon the facilities available for making the search and upon the ability and training of the searcher in making use of these facilities.

Libraries

The making of any comprehensive investigation necessarily requires that there shall be available a library containing the chemical literature properly classified and accessible for examination.

*Thesis, Armour Institute of Technology.

†Of the firm of Pennie, Davis, Marvin & Edmonds, counselors-at-law, 35 Nassau St., New York City.

Libraries of this character will be found in the larger cities and in many of the colleges, technical schools and universities, although the extent of the chemical literature, both book and periodical, will vary greatly in different libraries.

For many purposes the libraries of Washington offer facilities not elsewhere available. The Library of Congress is an excellent field of search because of its extensive number of publications and its card index catalog, and particularly if permission be obtained to examine the classified works in the stacks of the library. For making searches through the patent literature, both United States and foreign, the library of the Patent Office offers facilities nowhere else available in this country. The Smithsonian and Surgeon-General's libraries as well as those of the Geological Survey, Bureau of Mines and Department of Agriculture are likewise of special value in their respective fields.

Many of the public libraries of the larger cities, as well as libraries such as the John Crerar Library of Chicago, the Franklin Institute Library of Philadelphia and the Chemists' Club and Engineering Societies libraries of New York, also afford excellent fields of search.

In addition to these public libraries and libraries which are generally open to the public there are many private and special libraries, of associations, societies, corporations or individuals, which may contain valuable special collections along certain lines.

The importance and value of proper library service is well illustrated by the fact that at the annual meeting of the American Chemical Society at Buffalo (May 7 to 11, 1919), the program included a "Symposium on Library Service in Industrial Plants," with twelve different papers.¹

The publication, *Special Libraries*, of the Special Libraries Association contains much that is of interest from the general standpoint of library investigations, bibliographies, etc., and is to be recommended to those interested in such subjects.

In making use of a library's facilities the searcher may proceed in various ways—i.e., with the card index catalog, with the classified books on the shelves of the library, with the general reference works or with the periodical literature.

CARD INDEX CATALOGS

Every library of consequence has its card index catalog of the books and publications on the shelves of the library. The librarian is taught that "in any library the card catalog is the main bibliographical tool for that particular library" and that "good cataloging is the basis of all satisfactory service to the public."

In using the card index catalog the searcher will naturally look under the same general or special subjects or headings as in using the various indexes of chemical publications, although it may be necessary to look under more general, rather than or in addition to specific, subjects. After obtaining lists of the publications of the library along the lines in which he is interested he may have the publications brought to him, or he may in many libraries go to the shelves where the books themselves are classified.

Some libraries have special rooms where the more important scientific and technical periodicals and books are separately arranged for convenience of use. Thus in the New York Public Library publications relat-

ing to science and technology will be found in four adjacent rooms. Chemistry periodicals and books are in Room 118, physics, mathematics, geology, mining and metallurgy in Room 115, engineering periodicals in Room 117, engineering, patents, electricity, textiles and related subjects in Room 121. A single card index catalog serves as a guide to all the material in this division.

Again, certain libraries have special card index catalogs. The Patent Office at Washington has an extensive card index of the chemical literature, with a formula classification of organic chemical compounds similar to that of Richter's "Lexikon."

Some libraries also include in their card index catalogs reference to leading papers appearing in the current technical and scientific periodicals. The Engineering Library and Public Library of New York include references of this character.

In many fields of chemistry there are special books or monographs devoted to particular subjects and sometimes containing copious references to the patent and periodical literature. A search or investigation may be very materially shortened if such a work is found devoted to the particular subject of the investigation. These works will usually be referred to in the card index catalogs.

SHELF LISTS

From the card index catalog of the library the searcher can ascertain the classes where the particular books in which he is interested are classified. He may find that some of the books are in one class, some in another, still others in a third, and so on. If it is permissible to go to the shelves or stacks of the library he may find in these same classes still other books of interest which he did not find from the card index.

Information about the classification and arrangement of the books on the shelves, and even about books and publications relating to the particular field of the investigation, may frequently be obtained from the librarian or assistant in charge.

It is useful to keep in mind that both the Dewey decimal system of classification and that of the Library of Congress provide for the separate classification of science and technology. Thus in the Library of Congress classification Class Q relates to science and Class T to technology. Chemistry is classified in Class QD; chemical technology in Class TP. Agricultural chemistry is separately classified in Class S (agriculture); medical and pharmaceutical chemistry in Class R (medicine); physiological chemistry in Class QP (science); mineral industries, including metallurgy, fuels, etc., in Class TN (technology), etc. Some publications relating to chemical subjects are also classified in the class of economics (Class H), while others may be found in sets of Government publications or among series of bulletins or publications of universities, etc., and separately classified for that reason. For a complete search of the library's facilities, accordingly, it is important to use both the card index catalog and the shelf lists relating to the particular subjects of the investigation.

General Reference Works

For some purposes it is more profitable to begin with the general reference works, which will be found in considerable number in all of the larger and more important libraries, than with the card index catalog or the classified shelf lists. These general works include dictionaries, hand-books, encyclopædias, technologies,

¹See *J. Ind. Eng. Chem.*, vol. 11, pp. 578-589, June, 1919.

bibliographies, indexes of various kinds, etc., and are often separately classified from the rest of the chemical literature.

Some of these reference works will themselves be found to contain a great deal of information on many different subjects, particularly in the case of dictionaries and technologies, and some of the hand-books and encyclopædias; others will be found to consist mainly of indexes or bibliographies which direct the investigator to the periodical literature for further information. Sometimes reference works such as Beilstein or Richter, in organic chemistry, or Gmelin-Kraut or Abegg, in inorganic chemistry, will be the best place to start in making the investigation.

Some of the general reference works that may be used to advantage in making investigations are briefly referred to below. This list does not purport to be at all complete, but is intended rather as illustrative.

DICTIONARIES

Thorpe's "Dictionary of Applied Chemistry," published 1912-1913, in five volumes, is one of the best known and most valuable of the chemical dictionaries. It contains many valuable monographs and numerous references to the original literature.

Watt's "Dictionary of Chemistry," published 1892-1894, in four volumes, is an older but in some respects an even more valuable work.

Wurtz's "Dictionnaire de Chimie Pure et Appliquée," in three volumes, published in 1874, with its First Supplement, in two volumes, and its Second Supplement, in seven volumes (published 1892-1908), is another valuable reference work, and contains numerous references to the original literature.

ENCYCLOPÆDIAS

Freymy's "Encyclopédie Chimique," in ninety-three volumes, published 1882-1890, with an index volume (Table Alphabétique des Matières) published in 1899, is an elaborate work, but not as valuable as its size would indicate.

Ullmann's "Enzyklopädie der technischen Chemie," still incomplete, is a valuable work. Eight volumes are now available.

HAND-BOOKS

Gmelin's "Hand-Book of Chemistry" was translated by Watts, and published by the Cavendish Society, in eighteen volumes, the first six of which relate to inorganic chemistry and the last twelve to organic chemistry. The first volume was published in 1848, the eighteenth volume in 1871. A separate index volume was published in 1872. Seventy-seven periodicals are listed in the beginning of the first volume. The original German work of Gmelin was published in seven volumes, three relating to inorganic chemistry and four to organic chemistry.

This publication is one of the best and most valuable of the early reference works, and it contains, in digest or abstract form, reference to most of the important chemical literature prior to the middle of the Nineteenth Century.

There is a tendency among students and among some chemists to consider that the main strides in the advance of chemical knowledge have been within the last few years, but reference to Gmelin's Hand-Book shows that far more information was available half a century ago, both in inorganic and organic chemistry, than is commonly appreciated.

Perhaps the most elaborate and exhaustive digest of inorganic chemistry is Gmelin-Kraut's "Handbuch der anorganischen Chemie." This hand-book follows the same general plan as the earlier hand-books by Gmelin, giving a bibliography at the beginning of each subject and a discussion of the properties, methods of preparation and commercial methods of manufacture of the various metals and of their various compounds. About 170 periodicals are listed in the introductory portion of the first volume. The work is still incomplete, but the volumes which have been published and the fields which they cover, are indicated by the following table:

Vol. 1, Pt. 1, published 1907, 888 pages. Oxygen, Hydrogen, Helium, Argon, Neon, Krypton, Xenon, Nitrogen, Sulphur, Selenium.

Vol. 1, Pt. 2, published 1909, 441 pages. Fluorine, Chlorine, Bromine, Iodine.

Vol. 1, Pt. 3, published 1911, 907 pages. Phosphorus, Boron, Carbon.

Vol. 2, Pt. 1, published 1906, 512 pages. Potassium, Rubidium, Calcium, Lithium, Sodium.

Vol. 2, Pt. 2, published 1909, 726 pages. Barium, Strontium, Calcium, Magnesium, Glucinum, Aluminum.

Vol. 3, Pt. 1, published 1912, 1568 pages. Titanium, Silicon, Chromium, Tungsten, Molybdenum, Uranium.

Vol. 3, Pt. 2, published 1908, 1135 pages. Radio-active material (Uranium, Thorium, Radium, Polonium, Radio-Tellurium, Radio-active Lead, Actinium and Emanium, etc.), Vanadium, Manganese, Arsenic, Antimony, Tellurium, Bismuth.

Vol. 4, Pt. 1, published 1911, 1056 pages. Zinc, Cadmium, Indium, Gallium, Germanium, Tin, Thallium.

Vol. 5, Pt. 1, published 1909, 1595 pages. Nickel, Cobalt, Copper.

Vol. 5, Pt. 2, published 1914, 1752 pages. Silver, Gold, Mercury.

Vol. 5, Pt. 3, published 1915, 992 pages. Platinum.

The unpublished volumes of this Hand-book are as follows:

Vol. 4, Pt. 2, Lead, Iron.

Vol. 5, Pt. 4, Palladium, Rhodium, Iridium, Ruthenium, Osmium.

Vol. 6, Zirconium, Thorium, Tantalum, Niobium, Cerium, Lanthanum, Didymium, Neodymium, Praseodymium, Yttrium, Ytternium, Scandium, Erbium, Terbium.

OTHER HAND-BOOKS AND TREATISES

Abegg's "Handbuch der anorganischen Chemie," published 1905-1920, is another standard reference work on inorganic chemistry, and is perhaps better known than Gmelin-Kraut, although it also is incomplete.

Dammer's "Handbuch der anorganischen Chemie" is of similar character, though of earlier date.

Dammer's "Handbuch der Chemischen Technologie," 5 volumes, published 1895-1898, supplemented by "Chemische Technologie der Neuzeit," 3 volumes, 1910-1911, is a valuable survey of applied chemistry.

Roscoe and Schorlemmer's "Treatise of Chemistry," in English, and Moissan's "Traite der Chimie Minérale," in French, are also useful reference works.

GENERAL REFERENCE WORKS, ORGANIC CHEMISTRY

The most valuable work in the field of organic chemistry for use as a digest or reference work is Beilstein's "Handbuch der Organischen Chemie." Every organic chemist who has occasion to make investigations of the literature should be well acquainted with it.

The third edition was published in four volumes, from 1893 to 1899; the four supplemental volumes in 1901 to 1906; the supplemental volumes (Ergänzungsbände) following the same general plan as the original volumes. The fifth supplemental volume or index volume was also published in 1906. The scope of the work will be indicated from the following:

Vol. 1, published 1893, Fatty Series.

Vol. 2, published 1896, Aromatic Series: Hydrocarbons, Phenols, Alcohols, Acids.

Vol. 3, published 1897, Aromatic Series: Aldehydes, Ketones, Quinones, Camphor Products, Terpenes, Etheral Oils, Resins and Balsams, Glucosides, Bitter and Indifferent Substances, Dyestuffs, Tanning Material, Furan Series (Thiophenbodies), Alkaloids.

Vol. 4, published 1899, Aromatic Series, Bases Azoxy-, Azo-, Hydrazo-, Diazo-, Diazoamino-Derivatives, Albuminates, Phosphorus-, Antimony-, Arsenic-, Bismuth-Compounds, Boron and Silicon Compounds. Metallo-Organic Compounds.

Each volume is provided with an index, but these are superseded by the supplementary Index Volume 5, which gives an elaborate name index of the various compounds of organic chemistry described in the entire work.

Beilstein is supplemented by Richter's "Lexikon der Kohlenstoff-Verbindungen," in four parts, published in 1910-1912. This book is a collective index to the third edition of Beilstein and also contains numerous other literature references covering the period up to and including 1909.

A fourth edition of Beilstein, to consist of fifteen volumes, is being prepared by Bernard Prager and Paul Jacobson.² The volumes which have appeared to date are:

Vol. 1, published 1918, Acyclic Hydrocarbons, Hydroxy- and Carbonyl-Compounds.

Vol. 2, published 1920, Acyclic Carboxylic Acids.

Vol. 3, published 1921, Hydroxy- and Carbonyl-Carboxylic Acids.

This fourth edition is to include the literature up to the end of the year 1909.

Subsequent to 1909, Stelzner's "Literatur-Register der Organischen Chemie" covers the literature of organic chemistry for the period of 1910-1911 (vol. 1) and 1912-1913 (vol. 2).

Another index which should be mentioned in this connection is the card index catalog of the Patent Office at Washington. This catalog, so far as it relates to organic chemistry, has a system of classification by formula very similar to that of Richter's "Lexikon." This card index is not, of course, available except at Washington. It has been compiled under the direction of Dr. Edwin A. Hill, of the Classification Division of the Patent Office, and its character and scope are described in articles by Dr. Hill appearing in the *Journal of the American Chemical Society*, vol. 2, year 1900, pages 478-494; vol. 29, year 1907, pages 936-941; and vol. 34, year 1912, pages 416-418. It is also described in Appendix K of the report of the investigation of the United States Patent Office made by the President's Commission on Economy and Efficiency in 1912 (House of Representatives Document 1100, Sixty-Second Congress, Third Session).

BOLTON—SELECT BIBLIOGRAPHY OF CHEMISTRY

Another important work of a bibliographical character is the "Select Bibliography of Chemistry," by Henry C. Bolton, published by the Smithsonian Institution (Smithsonian Miscellaneous Collection Nos. 850, 1170 and 1253).

The first volume of this bibliography was published in 1893 and covers the period from 1492 to 1892. The first supplement, published in 1899, covers the period from 1492 to 1897, and includes works omitted from the first volume, together with those appearing up to the end of the year 1897. The character of this bibliography will be apparent from the following quotations from the preface of the first volume:

An attempt has been made in the following pages to collect the titles of the principal books on chemistry

published in Europe and America from the rise of the literature to the close of the year 1892. The term chemistry is taken in its fullest significance, and the Bibliography will be found to contain books in every department of chemical literature, pure and applied;

* * * * *

The Bibliography is confined, however, to independent works and their translations, and does not, as a rule, include Academic Dissertations (which are so numerous as to require a special catalogue), nor so-called "reprints" or "separates" (Separate-Abdrücke); of the latter only a few score are ordinarily printed and they must be regarded as belonging to periodicals. No attempt has been made to index the voluminous literature of periodicals except in the section of Biography as noted below.

* * * * *

To facilitate reference the work is divided into seven sections: I, Bibliography; II, Dictionaries; III, History; IV, Biography; V, Chemistry, pure and applied; VI, Alchemy, VII, Periodicals.

Altogether the first volume contains about twelve thousand titles, while the first supplement has fifty-five hundred more, making more than 17,500 in all. Of these titles 273 of the first volume and 95 of the supplement relate to bibliographies, while 327 of the first volume and 84 of the supplement relate to dictionaries and tables.

The third volume of this "Select Bibliography of Chemistry," by Bolton, relates to "Academic Dissertations." The dissertations are indexed under the authors' names, but the book is also provided with a subject-matter index. The nature of the work will be apparent from the following extracts from page 3:

This bibliography is not an index to the chemical dissertations that have appeared in periodicals, but a list of those that have been printed independently. When compiling the list of titles I was fortunate in securing permission to make copies of the card catalogues of two large collections of dissertations on chemistry, those in University Library, Strassburg, and those in the library of the United States Geological Survey, Washington City. I had also the opportunity of cataloguing several thousand dissertations deposited by the Smithsonian Institution in the Library of Congress; the latter were chiefly of German origin.

* * * * *

For the convenience of residents of the United States the dissertations found in the libraries of the Geological Survey and of the Smithsonian Institution are indicated by the letters "G. S." and "S. I." respectively.

CATALOG OF SCIENTIFIC PAPERS

This work, which is still incomplete, has been compiled and published by the Royal Society of London. It has properly been referred to as the most comprehensive index to general science ever attempted. The first six volumes, published 1867-1872, cover the period from 1800 to 1863. In the preface of vol. 1, it is said:

This catalog is intended to serve as an index to the titles and dates of scientific papers contained in the Transactions of societies, journals and other periodical works which have been published from the beginning of the present century to the end of the year 1863.

In the introduction of this same volume the subject-matter of the catalog is discussed in part as follows:

The following catalog is intended to contain the title of every scientific memoir which appears in the various Transactions and Proceedings of scientific societies, and in the scientific journals published within the time which it comprehends; with the reference, the date, the author's name and the number of pages in the memoir.

* * * * *

A list of the works indexed, nearly fourteen hundred in number, arranged alphabetically according to the contraction employed in the catalog, will be found at the end of the introduction.

* * * * *

The titles are arranged alphabetically according to

²For a discussion of the arrangement of compounds in this new edition see "Classifying Organic Compounds by the Prager-Jacobson System," by Donald W. MacArdle, *CHEM & MET. ENG.*, vol. 22, p. 256, Feb. 11, 1920.

the authors' names, the arrangement under the head of any one author being chronological.

The second series of the catalog, vols. 7 and 8, published 1877-1879, covers the period from 1864 to 1873. The third series, in three volumes (9 to 11), published 1891-1896, covers the period from 1874 to 1893. A supplementary volume, vol. 12, published in 1902, contains additional papers published between 1800 and 1883.

The papers of this supplementary volume were taken from more than 350 added periodicals, so that, with the nearly 1,400 periodicals indexed in the first volume, and with the 130 more added in vol. 6, the total number of periodicals indexed in the "Catalog of Scientific Papers" up to 1883 is between eighteen and nineteen hundred.

The fourth series of the catalog covers the period from 1884 to 1900. Vols. 13 to 16, for about half of the papers of the series, have so far been published, although their publication is of comparatively recent date (1914-1918). The remaining volumes are yet to appear.

When the catalog is completed, it will consist of an author catalog and a subject index covering the entire period from 1800 to 1900. That is, the volumes of the author catalog are to be supplemented by index volumes of subject-matter covering the entire period from 1800 to 1900. The subject indexes are to be issued separately for each of the seventeen sciences dealt with in the "International Catalog of Scientific Literature," and will be arranged in accordance with the schedules of the International Catalog. The index volumes of "Pure Mathematics, Mechanics and Physics" have thus far been published. Unfortunately the index volume for chemistry is not yet available. Until this volume is available, the "Catalog of Scientific Papers" cannot be readily searched, except as an author index. However, for investigating the various papers of any given author between the dates 1800 and 1900, the catalog undoubtedly furnishes the most complete and comprehensive single index available. When the subject-matter index volumes are likewise available, it will then be the most complete and one of the most valuable indexes of the chemical literature of the nineteenth century.

INTERNATIONAL CATALOG OF SCIENTIFIC LITERATURE

Beginning with the year 1901, the "International Catalog of Scientific Literature" was published as a continuation of the "Catalog of Scientific Papers" of the Royal Society of London, and it now appears annually, in seventeen volumes, for each of the seventeen sciences dealt with. These sciences or branches which are included in the catalog are as follows:

- A. Mathematics.
- B. Mechanics.
- C. Physics.
- D. Chemistry.
- E. Astronomy.
- F. Meteorology (including Terrestrial Magnetism).
- G. Mineralogy (including Petrology and Crystallography).
- H. Geology.
- J. Geography (Mathematical and Physical).
- K. Palæontology.
- L. General Biology.
- M. Botany.
- N. Zoology.
- O. Human Anatomy.
- P. Physical Anthropology.
- Q. Physiology (including experimental Psychology, Pharmacology and experimental Pathology).
- R. Bacteriology.

In the list of the journals, published as a separate volume in 1903, the surprising number of 4,673 journals is listed from twenty-five different countries. Germany leads with 1,308, France is second with 919, the

United States third with 539, and the United Kingdom fourth with 455, while Russia is fifth with 397.

It is, of course, evident that the field covered by the international catalog, as well as that covered by the "Catalog of Scientific Papers," is much broader than chemistry, but inasmuch as a separate volume appears annually for each science, the consideration of the portion of the catalog relating to chemistry does not involve a consideration of the portions of the catalog relating to other sciences. The "International Catalog" is one of the most valuable indexes of the chemical literature for the period which it covers (since 1900).

REPERTORIUM DER TECHNISCHEN JOURNAL LITERATUR

This work goes back to 1823, was edited by Schubarth for the volume covering the period 1823 to 1853, and by Kerl for the two volumes covering the periods 1854 to 1868 and 1869 to 1873. Beginning 1874 it appeared annually, and since 1877 it has been published by the German patent office. Prior to 1879 it was known as the "Repertorium der Technischen Literatur"; since 1879 it has been known as the "Repertorium der Technischen Journal Literatur."

It has had an author index since 1897 in addition to the subject index which it has always contained. The last volume of the "Repertorium" was published in 1908.

The general arrangement of the "Repertorium" is alphabetical, by subjects, and it contains reference to a large number of the leading articles appearing both in the German and in other periodicals for the current year. The field covered includes much that has no relation to chemistry and metallurgy, but it is nevertheless a valuable index for use in searches of the chemical and metallurgical literature. It is of course equally valuable in other fields than chemistry.

THE INDUSTRIAL ARTS INDEX

This index is published by the H. W. Wilson Co., 958-964 University Ave., New York. The plan of the index is set forth by the publishers in the following language:

The Industrial Arts Index is an indexing service to eighty-one technical journals which have been selected by our subscribers as the leaders in their respective fields. It reaches you in magazine form (instead of loose cards) ten times a year. The entries are arranged alphabetically by subject and repeated under place names when necessary. Every article of importance in these eighty-one magazines is indexed under as many subject headings as will bring out all points of interest, and cross-references direct to the searcher of allied subjects in other parts of the alphabet.

The rate for this service is based on the number of periodicals indexed for which you subscribe.

Annual volumes of the index have been published since 1912.

This index is not comparable with *Chemical Abstracts*, either in the scope of the field covered or in the detailed information which it gives, but it is nevertheless a useful index for many purposes, and one with which the searcher should be familiar. It includes much that is of general interest which is outside the field of chemical literature.

MINING WORLD INDEX

The "Mining World Index" of current literature was published from 1912 through 1916 by the Mining World Co. of Chicago. It was edited by the editor of the *Mining and Engineering World* and was published as "An International Bibliography of Mining and the Mining Sciences, compiled and revised semi-annually from the

index of the World's Current Literature, appearing weekly in *Mining and Engineering World*."

This index is of more particular interest to those making investigations of the mining and metallurgical literature, for the period which the index covers (i.e., 1912 to 1916).

ENGINEERING INDEX

The "Engineering Index" is an index which is likewise of more particular interest in connection with technical and engineering subjects, but it will nevertheless in some cases be found useful in those branches of applied chemistry which are included within its scope. Four volumes of the index cover the period from 1884 to 1905, and annual indexes have since been published. In 1906 the index covered about 250 technical and engineering journals in six different languages, about one-fourth of the periodicals indexed being in languages other than English.

Part II will be published in a subsequent issue.

British Report on Use of Tidal Power

In its third interim report to the President of the [government] Board of Trade the Water Power Resources Committee—of which Sir John Snell is chairman—deals solely with the question of utilizing the tides for power purposes. Its object is to urge the need of a more detailed technical inquiry into the subject than the committee itself is in a position to undertake. Of the tidal power schemes brought to its notice the greater number show no recognition of the very serious technical difficulties involved in harnessing the tides, and few have been worked out in detail. The committee has, however, had under consideration two tidal power schemes for the Severn Estuary, which, although preliminary, were based on investigation of the actual conditions of the site and were accompanied by estimates of cost.

The possibility of utilizing the tides of the Severn may almost be regarded as a test question; the tidal amplitude is large, the configuration of the estuary is well suited to the purpose; the physical characteristics of the land in the vicinity are such as to facilitate the construction of a high-level storage reservoir; and the adjoining industrial district is one in which the power requirements are already large, and the power supply is likely to be absorbed completely for industrial purposes.

PRELIMINARY EXAMINATION MADE

As a safeguard against undue optimism, the committee thought it desirable to carry out an independent preliminary examination of the subject on broad lines. A subcommittee consisting of Sir Philip Dawson and Prof. A. H. Gibson was constituted for this purpose. This subcommittee approached several of the leading firms of manufacturers of turbines and electric generators throughout the world with the object of obtaining particulars concerning low-head and variable-head turbines and electric generators suitable for tidal power schemes to enable it to frame an estimate of the possibility of utilizing the tides of the Severn. The results of the investigations which have been carried out support the view that energy can be generated and utilized at a favorable rate.

After giving careful consideration to the views expressed by the subcommittee the main committee finds that while on the information before it it is not in a

position to recommend the Severn scheme as a practical proposition, it is in unanimous agreement that the plan certainly cannot be dismissed as impracticable, and that further and more detailed technical inquiry into the subject of tidal power is amply justified and should be initiated without delay.

The utilization of tidal power involves the solution of many complex problems, and though the committee is of the opinion that a prima facie case has been made out for the Severn scheme, it must be pointed out that before a final pronouncement is possible a further investigation of a number of physical and technical questions—some of general interest and some peculiar to the conditions of the Severn—must be made.

SUMMARY OF CONCLUSIONS AND RECOMMENDATIONS

The conclusions arrived at are:

The difficulties to be overcome in harnessing the tides are so bound up with local conditions that it is essential that the general question of tidal power should be approached with reference to actual conditions obtaining at the same particular locality.

The technical information available in regard to the possibility of utilizing the tides in the Severn for the generation of power is not sufficiently precise to enable the committee to express a final opinion on the schemes which have been brought before it.

Preliminary estimates indicate, however, that if the Severn tides were used energy could be generated and utilized at a favorable rate, and that the power obtainable throughout an industrial day of ten hours would be of the order of 260,000 kw. and the consequent saving of coal would be from one and one-fourth to two and one-half million tons annually.

The committee recommends that:

The Board of Trade, in consultation with the Minister of Transport, should set up a special technical commission, consisting mainly of expert engineers and persons of scientific attainments, to investigate the possibility, from a commercial standpoint, of utilizing the tides for power purposes.

The inquiry should be pursued with special reference to the Severn Estuary; the commission should prepare a preliminary design and reasonably detailed estimates of cost of a tidal power scheme for that estuary, taking into consideration the desirability of making provision for road, railway and shipping facilities suited to the requirements and possibilities of the adjoining district.

The commission should have regard to any interests likely to be detrimentally affected and should consider and report upon the steps which might be taken to prevent or mitigate injury to any interest.

United States Sugar Production, 1920

According to a preliminary estimate made by the Department of Agriculture, beet sugar production in 1920 exceeded the former record crop of 1915 by 27 per cent and reached the figure of 2,219,200,000 lb. Production of cane sugar is estimated to have been 385,974,000 lb., so the total estimated sugar crop for United States was 2,605,174,000 lb. This was 15 per cent above record sugar production in 1916 and 53 per cent above 1919.

The sugar produced within the United States amounts to about one-quarter of the total consumption, which is estimated as 9,750,000,000 lb. for 1920, equivalent to 92 lb. per capita.

Electric Smelting of Pig Iron at Domnarfvet, Sweden

Early Operation at the Domnarfvet Iron Works and Conditions Leading to the Adoption of Electric Furnaces—Possibilities of Using Non-Charcoal Reducing Agents and Pit Instead of Shaft Furnaces Are Still in the Research Stage

BY BARON GERARD DE GEER
Manager, Domnarfvet Steel Works

STORA Kopparbergs Bergslags Aktiebolag, the company owning the Domnarfvet Iron Works, is the oldest in Sweden and most probably one of the oldest in the world. It has been estimated that the company was established about 1225, and there are still certain documents in existence, photographs of one of them being given in Fig. 2, setting forth special rights which had been granted the company by Swedish kings in the thirteenth century. At first, the smelting of copper at the Falun mine ("Stora Kopparberget," or the great copper mountain) was the main source of revenue, but during the following centuries iron and steel were also produced in increasing quantities. This industry was, as was the case with the iron industry of Sweden in general, based on the production of high-quality materials and was carried on at a great number of small plants. When railways had been built and the transportation conditions completely changed, these small places were concentrated to a large and more up-to-date plant, the Domnarfvet Iron Works.

EARLY OPERATIONS AT DOMNARFVET

This plant was built at the intersection of the Dal River and the railway which connects the works with its iron ores, as well as with Gothenburg, the most important harbor for import and export in Sweden. Wood required for making charcoal is transported in rafts on the Dal River, around the upper course of which the company's extensive forests are situated. Also power is obtained from the Dal River, which not far from Domnarfvet forms several important waterfalls (Fig. 1).

To begin with, the plant, in the same way as its predecessors, was intended for the manufacture of high-quality materials for export, but later the production was changed to ordinary iron for domestic consumption. There were several reasons for this. As Sweden became an industrial country, the demand for ordinary iron had increased and as certain grades were

protected by tariff, the conditions for domestic manufacture became more favorable. Moreover, it had become possible to use high-phosphorus ores in the basic steel processes invented at the end of the last century. Stora Kopparbergs Bergslags Aktiebolag is the owner of great deposits of very rich and suitably situated ore of this kind, which had heretofore been regarded as nearly valueless. Domnarfvet was therefore rebuilt, with the object in view to enter the domestic market and also to utilize the company's cheap high-phosphorus ores.

A basic bessemer plant was built with four 10-ton converters, and also a basic open-hearth plant with four 25- to 35-ton furnaces as shown on the plan, Fig. 3. As it was not possible to produce the required amount of pig iron in the original charcoal blast furnaces, these

FIG. 2. THE OLDEST ORIGINAL PURCHASE DEED
CONCERNING STORA KOPPARBERGET
Issued by the bishop Peter Elofsson, June 16, 1288, and relating to one-eighth of the company.

were rebuilt for operation with coke. Coke had to be imported from England or Germany, and was always of a poor quality on account of the long transportation and the frequent loading and unloading. We were equipped with reversing cogging mill, rail and shape mill, sheet and tin plate mills, wire mills and various merchant mills. With this equipment, the capacity of the plant was about 100,000 tons rolled products per year.

It soon became evident that this output was far too small and in nowise corresponded either to the selling possibilities or to the modern demand for mass production. When contemplating further construction, however, the question of obtaining fuel became vital. The plant had cheap ore and power, but the expensive and inferior coke was a real handicap in the competition with the imported iron. At this time (about 1910), electric pig iron smelting began to give commercial promise, so the company decided to postpone its new construction until it had been shown whether the increased requirement of pig iron could not be met by producing it with electric heat. This was thought to be well within the range of possibility, as the company could develop cheaply about 160,000 kw.

In order to decide this question, one 3,000-kw. shaft furnace of the Electrometals type and one 9,000-kw. Helfenstein furnace were built at Domnarfvet. The latter was a modified ferrosilicon furnace without a shaft. At about the same time the widely reported tests at Trollhättan were made with an Electrometals furnace, in which experiments all the iron works of Sweden were financially interested. After a few years' experimenting, it became evident that electric pig iron could easily compete with the Swedish high quality iron produced with charcoal, but not with ordinary iron produced in large quantities and that shaft furnaces were the most suitable, open furnaces being not as economical, as for instance when producing ferro-alloys.

On account of these facts Stora Kopparbergs Bergslags decided in 1914 to continue producing chiefly coke pig iron at Domnarfvet, and to build immediately a modern blast furnace with a daily capacity of about 500 tons. This was to be followed later by another similar blast furnace, and eventually also by coke ovens. At the same time it was, however, decided that the electric production of pig iron should not be discontinued, but kept up and further developed, as far as the supply of cheap power warranted. As the flow of water in the Dal River is considerably above normal during five or six months of the year, power can be obtained during this period at a very low price. The manufacture of steel would still be based on the basic bessemer process and the open-hearth plant was to be increased in capacity to take care of the increased amount of scrap. In these plans, the possibility of refining the basic bessemer metal in electric steel furnaces to improve its quality was also considered.

COKE SHORTAGE DRIVES PLANT TO ELECTRIC FURNACES

Construction of the new coke blast furnace was started immediately and at the same time some extensions were made to the melting and rolling shops to enable them to handle the increased quantity of iron. At this time, however, the world war broke out and upset all the calculations. The price of coke rose to an undreamed-of height, and at times it was impossible to obtain coke at all. As a matter of fact since 1917 the purchase price of one ton of coke has been higher than the cost to produce one ton of electric pig iron. To continue producing coke pig iron under such conditions was evidently impossible. At first we tried to mix coke and charcoal, but after a while the coke furnaces had to be shut down. Domnarfvet came to be in a very precarious condition, as it was impossible to obtain the pig iron required to keep the plant in operation. Still

FIG. 3. MAP OF DOMNARFVET STEEL WORKS

worse, the conclusion of peace and conditions following this did not improve the situation. There is no open market for coal and coke in Europe and everything indicates a permanent high price of coke.

Through these changed conditions the situation as regards coke iron and electric pig iron has become such as to give the latter a decided advantage. The only road open for Domnarfvet, not considering the alternative of shutting down completely, was to increase the production of electric pig iron. The construction of the new coke blast furnace, the foundations, storage yards and machinery of which were already finished, had to be stopped, and the installation of the electric furnaces hastened instead. However, water power must also be developed, which requires considerable time and capital.

In order to be able to increase the ingot production sooner, it has also been decided to install electric steel furnaces for melting cold scrap. Such a furnace, of 10 tons capacity, was finished in 1920 and two more were put in course of construction.

The electric pig iron process differs from the ordinary process, as is well known, in that the fuel required to heat and melt the charge is substituted by electric energy. In an electric pig iron furnace, only that quantity of charcoal is charged as is required for the reduction of the ore. As no air is blown in, the combustion of the carbon must be effected by means of the oxygen in the ore. The differences in design and operation between a blast furnace and an electric pig iron furnace are due to these conditions.

FIG. 4. CROSS-SECTION OF ELECTRIC PIG-IRON FURNACE PLANT

At the present time, six electric pig iron furnaces are built or are in the course of construction. The year of construction, type and capacity are given below:

Assuming an output of 3.6 tons pig iron per kw-yr., the capacity of the Electrometals furnaces would correspond to an output of about 80,000 tons per year. Such

Year	Type	Condition	Nominal Capacity of Transformers,*	
			Kw.	
1911	Electrometals		3,000	
1912	Helfenstein	Not operating in 1920.	9,000	
1915	Electrometals		5,500	
1918	Electrometals		4,000	
1919	Electrometals		4,500	
1920	Electrometals	Building in 1920.	5,000	
			31,000	

* Variation in these figures as quoted in the literature at various times and places is due to using figures purporting either the maximum or average input into the furnace, measured at different points.

an output, however, cannot be attained, as the supply of water allows full load only during certain periods.

A regulation of the drainage system of the Dal River by storing the water in the spring and autumn floods in the lakes to bring about a more uniform supply of power has already been started.

Fig. 4 shows furnace No. 4 at Domnarfvet. The upper part is similar to a blast furnace, but the lower part consists of a large crucible, the walls of which are connected with the shaft by means of a circular roof. Through this roof four, six or eight electrodes are inserted; they have a diameter of 600 to 700 mm. Gas is taken off at the top under the charging platform, cleaned in the usual manner, and part of it is blown into the furnace again through openings, as shown in the drawing, between the electrodes and immediately under the roof. A certain quantity of gas is therefore always circulating in the furnace.

The gas circulation is of very great importance for the proper operation of the furnace and attempts to dispense with it have failed. The gas cools the roof, thereby increasing its life, and also distributes the heat and the chemical reactions more evenly between the hearth and the shaft. The evolution of gas in an electric furnace is naturally considerably less than in a blast furnace, where about three times as large a quantity of carbon is burnt. The heat carried by the gas from the hearth up the shaft, as well as its ability

to perform the chemical reactions, will therefore be less. This is counterbalanced by blowing gas into the furnace. The carbon dioxide of this gas is immediately split up, forming carbon monoxide, which rises up in the shaft again unites with oxygen of the ore.

PRECAUTIONS FOR SUCCESSFUL OPERATION

In connection with an electric pig iron furnace, there are several factors which must be taken into consideration, but which are of no consequence in a blast furnace. The operation is very sensitive and requires careful attention, a fact perhaps better illustrated by a short account of some of the more common operating troubles.

It is of the utmost importance that the amount of carbon charged is carefully adjusted to the oxygen in the ore. If too much carbon is charged, the excess can not be burned, but accumulates in the hearth, causing "hot runs" with their accompanying troubles. If, on the other hand, insufficient carbon is charged, the reduction will be incomplete. The slag will be dark with a high

FIG. 1. DOMNARFVET STEEL WORKS
THE IRON TAPPING PIT

content of iron and the furnace will run cold. Disturbances of the state of equilibrium between carbon and oxygen may be caused either by variations in the composition of the charge or, which is more common, by variations in the carbon dioxide content of the gas. The ratio $\text{CO}_2 : \text{CO}$ is, as in a blast furnace, influenced by several factors, as for instance the temperature, the pressure, the size of the charcoal, etc. Assuming that the run is otherwise satisfactory, if this ratio is changed so that CO_2 is increased, there will be an excess of carbon burned up in the hearth. The amount of carbon charged is the same, but a certain part of this carbon will unite with more oxygen than before, and consequently a residue of carbon is obtained which cannot be burned. By accumulations of carbon in the hearth, the space required for the reactions becomes smaller, the temperature increases, and the rate of melting decreases. This causes the CO_2 content to increase still more and conditions become still worse. Finally, the zone of reaction will come up close to the shaft and the energy put into the furnace will not cover the losses. The furnace will then come to a standstill.

If for some reason the ratio $\text{CO}_2 : \text{CO}$ is changed so that CO_2 is decreased, the conditions will be just the opposite. The rate of melting will increase, the pig iron will become cold, and the slag will be very unsatisfactory. Also in this case a minor disturbance will show a tendency to multiply itself, due to the fact that the increased rate of melting causes the percentage of CO_2 to decrease still more.

The problem of overcoming these troubles presented a good deal of difficulty at the start. This was particularly the case with hot runs with an excess of carbon in the hearth. To decrease the carbon or to increase the ore, as would be done in a blast furnace, proved to be ineffective. It was difficult to make the proper adjustment, and, through the decreased rate of melting, it took a long time before any change in the charge could make itself felt in the hearth. Frequently it was only a temporary disturbance which caused the trouble, and if the charge was changed permanently, it might cause the furnace to change from one extremity to the other. While adjusting the operation in this way, the equilibrium of the furnace proved to be very unstable and during long periods hot runs might change to cold runs and vice versa, with excess or want of carbon in the hearth.

The simplest way to correct hot runs for instance would be to charge a certain quantity of ore directly into the hearth, corresponding to the excess of carbon. It has also been suggested to combat it by sprinkling water on the charge through the gas intakes. Both these methods have been tried, but they are difficult of application. It has been found that the best way to restore equilibrium between carbon and oxygen is to add only one or two charges of ore or charcoal without making any permanent change in the burden. This is changed only when the furnace shows a decided tendency to run hot or cold. It would of course be better to prevent the disturbances altogether, and it is advisable to observe carefully the composition of the gas and at the first sign of departure from normal limits make the necessary adjustments.

Another peculiarity with the electric shaft furnace is the difficulty of regulating the temperature of the pig iron when the furnace is running normally. An increase in the amperage does not increase the temperature of the iron tapped, but only increases the rate of melting. It is true that an increase of carbon in the charge will make hotter iron, but at the same time, due to excess carbon in the hearth, it will cause grave disturbances. It seems that pig iron attains only that temperature which is necessary for the reactions in the hearth to take place. The superheating desirable to avoid losses in runners and skulls during tapping and transportation of the iron is often very difficult to obtain.

OPERATING DATA

In the accompanying table is a tabulation of analyses of raw materials and products at the electric furnaces at Domnarfvet together with some operating data.

The ore is taken from Grangesberg deposits and is a mixture of magnetite and specular hematite. Phosphorus analyzes about 1 per cent, somewhat too low to obtain the desired content of phosphorus in the pig iron. Some apatite is therefore generally added, also some manganese ore or slag high in manganese to raise the manganese content. As the ore, as well as the charcoal, is practically free from sulphur, and the silica content of the ore is relatively low, only a small amount of limestone is needed as addition to the charge in order to obtain the desired composition of the slag, which in turn is used for the manufacture of cement.

Gas from electric furnaces is considerably richer than ordinary blast-furnace gas and is an appreciable item on the credit side of the electric furnace account. The excess of gas has been estimated at 400 to 600 cu. m. per ton of pig iron. At Domnarfvet it is used for burn-

ing limestone or, mixed with producer gas, in open-hearth furnaces. On account of its high content of carbon monoxide, this gas is very poisonous and great care must be exercised to guard against leaks in the tanks and piping.

NON-CHARCOAL REDUCING AGENTS

A question which is of vital importance for the future of the electric pig iron furnaces is the possibility of using some other reducing agent than charcoal. If the electric iron industry at Domnarfvet is to be further developed, its maximum capacity will be determined by the supply of charcoal, not of power, since supply of the former will give out sooner than the supply of the latter. On account of the much increased demand for paper and paper pulp, the competition for wood for making charcoal has become very active. The prices threaten to increase so as to make the manufacture of charcoal prohibitive and the charcoal ovens will soon be run only on wood refuse.

If the utility of the electric pig iron process in Sweden is to be limited by the amount of charcoal available, it will be so much more circumscribed in other countries which have a large supply of water power but lack charcoal. Other reducing agents which may be considered are coke and anthracite.

Tests with coke have been made at Domnarfvet. It was shown that a mixture of coke and charcoal, with 50 per cent of each, could be used without causing trouble, but when a higher percentage of coke, or coke alone was used, the results obtained were poor. The output decreased considerably and the power consumption per ton of pig iron increased. This fact may be explained by the comparatively low electric resistance and high density of coke as compared with charcoal, resulting in decreased velocity of reaction. Another inconvenience consisted in the tendency of the coke to graphitize at the high temperature prevailing around the arcs. Graphitized coke reacts only very slowly with the oxygen in the ore. Hot runs, with accompanying evils, became on account of this still worse, as once an excess of carbon was obtained it was difficult to burn. Actual tests with coke at the Domnarfvet electric furnaces have definitely proved this fact, that the troubles on account of hot runs were considerably greater when running with coke than with charcoal.

With this exception, there were no technical difficulties in connection with operation with coke, but our economical results were poor on account of the lowered production and the increased power consumption. To

FIG. 6. DOMNARFVET STEEL WORKS
Houses for Workmen

pronounce the Electrometals furnaces as unsuitable for operation with coke or anthracite on account of these tests would be incorrect. Domnarfvet furnaces were designed in view of operation with charcoal exclusively and it is evident that operation with coke requires a somewhat different design, as is the case with blast furnaces. What this difference is is not yet determined, at least not on the basis of actual tests. An answer to this question will doubtless be had in the near future, as it is said that plans to try out coke are maturing at several places.

PIT VERSUS SHAFT FURNACES

Another interesting question in connection with electric smelting of ore is the possibility of using simpler and cheaper furnaces than the relatively complicated shaft furnaces, such as the open furnace of about the same type that is used for making ferrosilicon. Although tests with this kind of furnace considerably antedated the tests with shaft furnaces, these latter furnaces have been successfully developed, while the open furnaces have not yet passed the experimental stage. It might be justly asked why pig iron cannot be made in an open furnace as well as ferrosilicon, which is more difficult to reduce. The answer is that technically there is no difficulty in making iron in an open furnace, but economically it is more advantageous to make it in a shaft furnace. Under normal conditions—i.e., with low fuel prices—the difference in the cost of production between blast-furnace iron and electric pig iron is so small that only a very small difference in favor of the former will make the latter impossible. In an open furnace, the consumption of charcoal and power are both greater than in a shaft furnace. The lower temperature of the escaping gases and their higher CO₂ content mean a more effective utilization of power as well as of charcoal. In addition, the excess gas may be used for generating power or heat, something which is done at all large electric pig iron plants. Against these advantages, the open furnace can show a lower cost of installation and possibly a certain adaptation for a variation in the grade of iron produced. Such a furnace may for instance without any difficulty be made to produce pig iron instead of ferrosilicon. However, the possibilities may be of great practical importance in isolated cases.

Domnarfvet is probably one of the few plants where both types of furnaces have been run at the same time on a large scale. The tests were decidedly in favor of the shaft furnaces, and future installations would on that basis probably be made along the same general lines.

By the use of the foregoing table¹ about 330 inter-conversions among twenty-six of the standard engineering units of measure can be directly estimated from the alignment chart to three significant figures or calculated by simple multiplication to six figures. The multiplier factor given in the table is located on the center scale "A" giving the point which when aligned with any number point on "C1" determines the product on

"C." Imperfections in the scale due to lack of precision in printing should be checked at intervals along "A" scale by actual division of "C" by "C1," the lines being left out so that the reader can do this. A line scratched on a transparent celluloid triangle gives the best medium for making alignments.

When volume and weight interconversions are given, water is the medium the calculations are based upon. By the introduction of specific gravity factors the medium can be changed, giving the weight of any volume of any material, etc.

Extraction of Juice From the Sugar Beet

Brief Outline of Modern Practice in the Beet-Sugar Refinery—Fluming and Washing—
Design of Equipment—Diffusion Cell and Battery—Effect of
Temperature on Purity

BY WALLACE MONTGOMERY

THE advances made in chemical engineering during the past few years have not been adopted as readily by sugar manufacturers as by other industrial concerns. They have recently awakened to the fact, which is made evident by their increased rate of production as compared with earlier years. The harvesting season being short, the factories are forced to lie idle for many months of the year. This fostered the tendency on the part of the owners to be conservative regarding changes unless thoroughly proved of value.

The manner of harvesting and transporting beets has changed considerably, but there is still unlimited opportunity for improvements. The manufacturing operations proper have to deal with the beet after it has been delivered into the storage bins, and the resulting products from the working up of the beet.

The beets are flumed into the factory by water from the tail pipes of condensers, the amount of which water should not be less than 950 to 1,000 per cent on beets handled. A larger quantity insures an adequate supply of beets at all times. The fluming of the beets is beneficial in that much of the adhering particles of the dirt is removed, also trash and tops are separated. There is some water absorption during the time the beets enter the water until they are taken up in elevator to scales. This has been found to vary with the temperature of the water and the class of beet, though 0.2 per cent is an approximate figure. The beets pass over separators to remove rocks or any foreign substance.

BEET WATER

A drawing of one type of equipment for removing the beets from the flume and placing them in the washer is shown in Fig. 1. The wheel revolves and picks up the beets, allowing them to drop into the washer, from which they are worked toward the farther end by paddles, a continual stream of water flowing through the washer at all times. From the washer the beets pass over a picking table or series of rolls as in this particular case, these rolls being set just far enough apart to keep the beets moving but allowing any small pieces or tailings to drop through to a separator directly below.

For a number of years the tailings and broken pieces of the beets removed from the picker were either thrown away or used as feed for hogs. At present it is the usual practice to work them up along with the

whole beets. The quantity of tailings will vary greatly, as also will the sugar content. A specific case in which the author conducted a test over practically an entire campaign gave the following results:

	Per Cent
Tailings on beets worked.....	0.2
Sugar in tailings.....	7.40
Apparent purity.....	80.00

Scrolls are also used in elevating beets from flume to pickers or washer, and one large American factory uses an air lift successfully.

From the rolls or picking table the beets are discharged into an elevator and are then carried up to the top floor of the factory, where they are discharged into a hopper and through some form of scales where the weight for the factory control is obtained. The checking of the scales is very important, as a slight error here throws off the entire results throughout the house.

From the scales the beets drop into a hopper and feed into the cutters, where they are sliced into V-shaped slices called cossettes. The cossettes enter the diffusion cells, where the first important step in sugar manufacture takes place—the extraction of the sugar in the cossettes by diffusion—and the handling of the diffusion juice calls for continuous control and care to prevent unnecessary losses and to keep the unavoidable losses within reasonable limits.

Fig. 2 shows the construction of a diffusion cell.

FIG. 1. BEET WHEEL WASHER AND ELEVATOR

These cells are arranged either circularly or in a straight line, known as circular battery and straight battery. Both have advantages, though in economy of space and ease of manipulation a circular battery is to be preferred.

There are a number of processes and methods of diffusion. That of Naudet has recently attracted most attention. Fig. 3 shows a Naudet battery in plan.

The losses taking place at the batteries may be calculated from the following data obtained from the laboratory where analyses are being made continuously upon all products.

	Per Cent
Sucrose in beets.....	18.50
Purity (apparent).....	84.00
Battery Losses:	Per Cent on Beets
Sugar in pulp.....	0.16
Sugar in pulp water	0.05
Total known loss	0.21
Total sugar entering house = 18.50 — 0.21 = 18.29 per cent	
Giving a battery extraction of 98.86 per cent of suger in beets and a loss of 1.14 per cent of sugar in beets.	
Assuming the analysis of the diffusion juice to be:	
Brix, deg.	14.00
Per cent sucrose	11.69
Apparent purity, per cent	83.50
Ash, per cent	0.62
Then the total solids entering house would be	
$18.29 \times \frac{100}{83.50} = 21.91$ per cent on beets	
Non-sugars entering house are:	
$21.91 - 18.29 = 3.62$ per cent on beets	
Organic non-sugars are:	
$3.62 - 0.62 = 3.00$ per cent on beets	

THE PERCENTAGE DRAFT

The percentage draft or amount of juice drawn from the diffusion battery varies from 125 to 160 per cent on

FIG. 2. DIFFUSION CELLS

beets and in some cases may be even higher. From our previous calculation the draft would be

$\frac{18.29}{11.69} \times 100 = 156.5$ per cent

The percentage draft is held at a point where the losses are the lowest and the juice still of sufficient density to not require excessive evaporation.

The amount of steam necessary for diffusion varies considerably, due to the temperature of battery water, temperature of beets and temperature of juice drawn. Usually 2.5 to 5.5 per cent on beets worked will suffice.

To calculate the time of diffusion or the average time one cell remains in circulation we must know the total number of cells made each twelve hours and the number of cells over which circulation is carried, assuming that on a 14-cell battery 100 cells were made in twelve hours and the circulation carried over twelve cells.

Then time of diffusion = $\frac{14}{100} \times 12 = 1.68$, or 1 hour 41 min.

FIG. 3. PLAN OF NAUDET BATTERY

By per cent fill in battery is understood the pounds of beets per each 100-lb. capacity of the cell space of water.

Assuming cell capacity to be 200 cu.ft., or 56.6 hectoliters,
Number of cells worked 170
Tons beets worked 600
Cell capacity, 200 cu.ft. $\times$ 62.3 = 12,460 lb. water
Tons beets per cell = $\frac{600}{170} = 7,040$ lb.
Percentage fill = $\frac{7,040}{12,460} = 56.5$ per cent

TEMPERATURE AND PURITY OF PRODUCT

The varying purity and sugar per cent in the different cells is shown by Fig. 4. This varies, of course, but under ordinary conditions the curve is approximately the same. The figures above the curve denote the temperature of each cell, and those below indicate thr percentage of sucrose in each cell at the time samples were taken.

The regulation of temperature is of the utmost importance and in no case should it exceed 97 deg. C. The beets will to a certain extent determine what temperatures may be carried, because with a well-matured beet high temperature causes the pulp to become mushy and very hard to dump from the cells. With firm beets not quite ripe higher temperatures may be carried,

FIG. 4. CURVE SHOWING VARYING PURITIES OF BATTERY

though the amount of gums freed from the pulp is very detrimental to the further working up of juice and so offsets any gain in extraction.

The pulp of diffused cossettes is 80 per cent by weight on beets worked, while waste, the water remaining in the cell at time of discharging, amounts to 150 per cent on the weight of the beets. The discharging of the exhausted cossettes in nearly all modern factories is done by mechanical means, the bottom door being operated by hydraulic pressure governed by an operator above. Fig. 2 shows an old type door operated by hand, which in closing and locking properly takes too much time. One of the most ingenious improvements relating to the battery is the water inflated gasket for bottom of cell doors. This consists of a heavy circular rubber tube on the same order as an inner tube for automobile tires. When the door is to be opened the pressure is released from the gasket. After closing the door again, the gasket is inflated, thereby making a tight joint and preventing leakage from the cell bottom, the door and bottom of cell being grooved to receive this gasket. No

attention is required, only examination occasionally. The pulp and waste water are removed from battery pit by centrifugal pumps and sent to a silo, where the water drains off and the pulp remains to be used as cattle feed, or else it is sent directly to the drying department, where it passes through a press or series of presses. It is then dried in large rotary driers heated by steam or hot gases obtained from furnaces in which oil is burned.

The pulp, as it enters the drier is of the following composition:

	Per Cent
Moisture	93.0 — 95.0
Sucrose	0.32 — 0.45

After passing through the presses the moisture is about 83 to 85 per cent, and from the driers ready for sacking contains only 11.5 to 12.5 per cent moisture, and about 32 to 35 per cent will pass through a 10-mesh sieve. The pulp contains about 0.50 to 0.55 per cent sugar.

Heat of Dissociation of Iron Pyrites

BY HEIHACHI KAMURA

THE object of this investigation was to find the heat absorbed in the decomposition of iron pyrites, FeS_2 , into FeS and sulphur vapor. Previous attempts to measure this calorimetrically had not succeeded, and up to the present the heat of formation of pyrites from FeS and sulphur vapor is unknown.

Following the suggestion of Dr. J. W. Richards, the author measured the decomposition pressures at which sulphur vapor is given off by iron pyrites at different temperatures, with the object of finding the decomposition pressure curve, and thence deducing thermodynamically the heat absorbed in the decomposition.

Temperatures were measured by a platinum-iridium thermocouple. Pressures were measured directly upon a mercury pressure gage.

The experimental results are contained in the accompanying diagrams. Fig. 1 is the plot of the pressure in millimeters of mercury against the temperature in degrees C.¹

Fig. 2 is a plot of the results showing logarithm of the pressure against the reciprocal of the absolute temperature. It will be seen that they conform reasonably well to a straight line relation between these quantities.

Fig. 3 shows the plot of the same observations extended to zero value of $\frac{1}{T}$, in order to illustrate the relation in its entirety, corresponding to

$$\log p = -\frac{8145}{T} + 11.50$$

which is the formula deducible from my experimental data.

The constant 11.50 in the above equation corresponds fairly well with that obtained for other similar decomposition pressure equations, there being a tendency for this value to lie between 9 and 12 for all decomposition pressures. The thermodynamic discussion of this formula makes Q , the heat of decomposition per molecular volume of sulphur vapor formed, $4.57 \times 8,145 = 37,223$, corresponding to the heat value of the equation

¹The results of similar experiments recorded by Messrs. Allen and Lombard in the *American Journal of Science*, 1917, vol. 43, p. 175, are shown for comparison.

We can, therefore, write the value of the heat absorbed per atom of sulphur or, rather, conversely, the heat evolved in the combination expressed thermochemically as follows:

Metallurgical Department,
Lehigh University.

Who Is Entitled to Inventions?

BY CHESLA C. SHERLOCK

INVENTIONS and the right to ownership in them have caused a good deal of litigation in our courts. The question of ownership in an invention must be determined before the right to the patent can be thoroughly established. And it is because of the value of the patent monopoly that the question of ownership is so bitterly contested before the courts.

The patent laws contemplated that the actual inventor of the new appliance should be the sole person entitled to the letters patent, and the law is so worded. It was not contemplated that the ownership could be vested in anyone but the actual inventor, especially in the earlier days of our patent history. But of later years it became apparent that persons other than the actual inventor might have a legitimate interest in the ownership of the fruits of his skill or inventive genius.

RIGHTS OF INVENTOR WHEN HE IS HIRED TO WORK ON INVENTION

The most common case is where an employer hires one of an inventive turn of mind on a stipulated salary to work on some appliance or invention for the benefit of the employer's trade or business. If the inventor fails to bring forth the desired invention, then the employer is the loser in the salary paid to the employee during his period of experimentation.

But suppose that the employed inventor does, in fact, succeed in bringing forth the invention which the employer has asked for? Suppose that the employer has paid him the stipulated salary, but that when the invention is a success the inventor claims that the invention belongs to him solely and he refuses to assign the patent rights or the ownership in it to the employer? What are the rights of the respective parties?

This is a question which has been so thoroughly threshed out by the courts that the principles are generally accepted as being settled. It will not be necessary for us to cite cases, unless someone comes forward and wants them to substantiate the principles here announced as to the rights of the respective parties.

COURTS SEEK TO PROTECT ACTUAL INVENTOR

The courts will make every effort to preserve the rights in the invention in the actual inventor. This does not mean that they will seek to ignore existing agreements or contracts or fail to take into consideration all the facts and circumstances surrounding each case.

The point is that the actual inventor is the one to be protected in all cases consistent with justice. He is the one for whom the whole theory of patent rights and privileges was first promulgated; he is the one to be favored and secured in any rights in danger.

But where an employer has expressly contracted with an inventor prior to the invention of a given appliance, method or machine, upon the express understanding that any rights which the inventor may have in the invention are to become the sole property of such employer in consideration of the stipulated salary, then the courts will take cognizance of this agreement and the right of ownership in the invention rests in the employer. This is practically the only case in which the employer of an inventor can step in and acquire any rights in the invention. And it is well to mark this fact.

Take a case where an employee, not expressly employed

to perfect an invention, does bring forth an invention having commercial value. Does the employer have a right to share in the ownership on the theory that the employee learned things of advantage or used the knowledge and skill obtained on the employer's time in perfecting his invention?

EMPLOYER HAS NO RIGHT IN EMPLOYEE'S INVENTION EXCEPT BY SPECIAL PRIOR CONTRACT

It is the general rule that the employer has no right in the inventions of an employee unless they have expressly contracted concerning said invention. Employees are not deprived of their rights to an invention merely because they happen to be in the employ of another at the time they perfect their patentable ideas. To recognize any such rule would serve to defeat the very purpose for which the patent privileges were originally granted under the Constitution.

Inventions arising casually out of an employee's association with an employer, then, are not subject to any property rights vesting in the employer. The only instance where an employer can secure an interest in an invention perfected by an employee is for him to enter into a valid contract which grants him such right *prior* to the perfection of said invention, or an assignment of the rights in the patent subsequent to it.

CONTRACT MUST BE WRITTEN AND ENFORCEABLE, NOT A MERE UNDERSTANDING

It is well to pause right here and make it plain that this agreement must be in the form of a contract which can be enforced in the courts. A mere mutual understanding that the employer is to have all rights or a share in the ownership of an invention which the employee is to bring forth is not sufficient to confer that right upon the employer. The presumption in such a case would be against the employer and in favor of the actual inventor.

The contract must be a written agreement and, as such, enforceable at law. This means that it must be for a valid consideration, made by proper parties and for a lawful object. Failing in this, the employer will only be the loser and there is no redress for the wrongs he suffers.

If the employee has permitted his employer to use the invention, the law presumes that the employee or inventor has granted a license to such employer for the use of said invention. And this license or right to use will continue even after the employee-inventor has left the employment of the original employer.

Indigo in the Dutch East Indies

Indigo is grown on about forty estates in Java, as well as by the natives. The estate indigo contains from 60 to 80 per cent of indigotine. The native product averages only $\frac{1}{4}$ to 1 per cent of indigotine, and is for the greater part used in the island, principally for battiking, while the overproduction usually finds a market in Singapore. Before the war most of the dry indigo went direct to the Netherlands and the wet product to Singapore. In 1917 Japan entered the market for both the wet and dry product, and in the following two years took the bulk of the dry product. During 1920 Singapore was an important market for the product. The United States bought a small quantity of dry indigo in 1917, increasing its purchases in the following year, but has since been out of the market.

Cobalt Brasses*

Cobalt in Brass Acts Much Like Nickel in Brass, Despite Their Different Influence on Steel—Of All the Elements Investigated, Cobalt Is Unique in Possessing a Variable Coefficient of Equivalence

By LEON GUILLET

THE following study was made with the view of comparing the rôle of cobalt with that of nickel in Cu:Zn alloys, as presented in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 24, p. 261.

It is first necessary to give the binary diagrams of Cu:Ni, Cu:Co, Zn:Ni and Zn:Co. According to the most recent works the constitution of these different alloys are:

COPPER: NICKEL

This is a classical diagram and according to Guertler and Tammann¹ is as shown in Fig. 1. The liquidus is formed of a single branch of a curve without maximum or minimum and the solidus consists of a single branch located slightly below. Two lines representing the magnetic transformation can be noted below 320 deg. C., but no other change appears in the solid. Magnetic transformation point is rapidly lowered as the copper content is increased, varying from 330 deg. C. (626 deg. F.) to 0 deg. C. (32 deg. F.), the copper being respectively 0 and 48 per cent.

COPPER: COBALT

The copper:cobalt diagram (Fig. 2) is quite different,² approaching that for copper:iron. The liquidus indicates a transition point near pure copper. The upper branch of the liquidus is quite irregular and all alloys containing up to 80 per cent of copper melt above 1,300 deg. C. (2,375 deg. F.). The solidus is formed by a branch starting at the fusion point of cobalt (1,490 deg. C., or 2,714 deg. F.) and reaching the horizontal line corresponding to the transition point (1,110 deg. C., or 1,850 deg. F.) at a point where the copper content of the solid solution is 12 per cent. A short curved branch also starts on the transition horizontal at copper 97 per cent and ends at the melting point of pure copper.

Immediately below the solidus, in the neighborhood of pure cobalt is found a solid solution between β non-magnetic cobalt and copper (constituent I). In the neighborhood of pure copper, a zone of small extent locates a non-magnetic copper:cobalt solution (constituent II). A zone of far greater extent below the horizontal part of the solidus consists of a heterogeneous mixture of constituents I and II. But the non-magnetic solid solution becomes magnetic at higher temperatures. We therefore have various transformation lines as follows: Cobalt loses its magnetism at 1,159 deg. C. (2,118 deg. F.). This transformation point in constituent I is lowered to about 1,050 deg. C. (1,920 deg. F.). After this transformation the alloys contain a constituent III which is simply solid solution I, consisting of copper in cobalt, become magnetic. There is

also a very small zone of constituents I + III. At the extreme right of the diagram, the non-magnetic solid solution II becomes magnetic at temperatures which are approximately determined as shown by region IV.

The horizontal line at 1,050 deg. C. (1,920 deg. F.) separates mixtures of solutions I and II from mixtures of zones III + II, and the horizontal line at 955 deg. C. (1,751 deg. F.) separates the latter from a zone consisting of a mixture of solutions III + IV. It is to be noted that in the last region both solid solutions are magnetic, in the next above only the cobalt-rich solution is magnetic, and in the zone just below the solidus neither constituent is magnetic.

ZINC: NICKEL

Equilibrium in the zinc:nickel system has been studied by Tagel³ despite difficulties caused by volatilization of the zinc. Researches were made first on alloys containing up to 24 per cent nickel, but the diagram shown in Fig. 3 has subsequently been completed. The liquidus, starting from the melting point of nickel, is

³Z. anorg. allgem. Chem., vol. 57, p. 34; *Revue de Métallurgie*, vol. 4, p. 781; vol. 5, p. 413.

FIG. 1. BINARY DIAGRAM COPPER: NICKEL ALLOY

*From *Revue de Métallurgie*, vol. 17, No. 7, p. 494 (1920).

¹Z. anorg. allgem. Chem., vol. 52, p. 25 (1907).

²Salmen, Z. anorg. allgem. Chem., vol. 57, p. 1 (1908).

FIG. 2. BINARY DIAGRAM COPPER: COBALT ALLOY

lowered rapidly and shows a transition point at about 54 per cent zinc and 1,035 deg. C. (1,895 deg. F.), a eutectic at 870 deg. C. (1,598 deg. F.) and 73 per cent zinc and the maximum corresponding to the compound NiZn_2 fusing at 876 deg. C. (1,609 deg. F.). Beyond this maximum the liquidus drops rapidly to the melting point of zinc (419 deg. C., or 786 deg. F.).

The solidus is formed of a line starting from the melting point of pure nickel and ends in the transition horizontal at 35 per cent zinc. A new oblique line starts at approximately the transition point on the liquidus. This branch reaches the eutectic horizontal at 61 per cent zinc and this horizontal extends a little distance beyond the eutectic point. The solidus is then formed of two curved branches reaching the maximum on the liquidus at the compound NiZn_2 , the right hand being extremely steep, reaching horizontal at the melting point of zinc, following this horizontal to the end of the diagram.

The conformation of liquidus and solidus indicates the existence of: Region I, a solid solution of zinc in β nickel. Region V, a solid solution below the transition horizontal, and which may be due to a suppositious compound, NiZn . Region VII, the solid solution of NiZn_2 . A first eutectic between constituents V and VII. A second eutectic between pure β zinc and the solution containing compound NiZn_2 . (Zone VII + β Zn.)

Study of the diagram also shows other transformation points, some of which are very interesting.

At the nickel side the magnetic transformation in the solid solution is depressed until for 20 per cent nickel it does not occur above ordinary temperature. Constituent II is therefore a solid solution of zinc in magnetic nickel. At the zinc side the transformation takes place

at a constant temperature (360 deg. C., or 680 deg. F.) because the zinc retains its identity in alloys containing as high as 10 per cent nickel. The solid solution V forms a eutectoid with 59 per cent zinc at 655 deg. C. (1,211 deg. F.) between solid solution VII and constituent VI (compound NiZn). This is a good example of a chemical compound formed during the decomposition of a solid solution.

ZINC: COBALT

Zinc: cobalt has been studied by Lew Konja' as far as alloys containing 40 per cent cobalt. This portion of the diagram (Fig. 4) is very similar to the similar end of the zinc: nickel diagram (Fig. 3).

The liquidus starts from pure zinc and rises rapidly. Higher than 20 per cent cobalt the diagram could not be traced with precision. The solidus consists of a horizontal line at 414 deg. C. (777 deg. F.) starting from 87 per cent Zn and reaching over nearly to pure zinc. It would seem that the eutectic does not correspond to exactly pure zinc, but is an alloy containing about 0.5 per cent cobalt.

Constituent I is the pure β zinc; the eutectic would be formed of β zinc and a constituent III, a poorly defined zinc: cobalt solid solution. Zone III + β Zn separated by the horizontal line at 360 deg. C. from zone III + α Zn do not differ except by the allotropic state of the zinc.

To summarize:

Copper: nickel alloys are formed of a single solid solution, which is non-magnetic or magnetic depending upon the content of nickel.

Copper: cobalt alloys are composed of two conjugate

¹Z. anorg. allgem. Chem., vol. 59, p. 293 (1908).

FIG. 3. BINARY DIAGRAM ZINC: NICKEL ALLOY

solid solutions varying somewhat in composition, both of which exist in the magnetic and non-magnetic forms at the proper temperatures.

Zinc:nickel alloys exist in solid solutions extending from pure nickel to 50 per cent zinc. Nickel appears to be insoluble in zinc, however. There are also two compounds, NiZn and NiZn₃, the last one appearing in solid solution in nearly all the zinc-rich alloys.

Zinc:cobalt alloys. The constitution is known only in the neighborhood of pure zinc; they are formed of pure zinc and of an imperfectly understood solid solution, as summarized in Fig. 4.

ALLOYS TESTED

In the study of cobalt brasses, the tests have been made under the same conditions as for nickel brasses.⁵

Table I shows the composition of the alloys tested. Three series were studied containing respectively about 70, 60 and 55 per cent copper, the cobalt increasing in

FIG. 4. BINARY DIAGRAM
ZINC: COBALT ALLOY

Fig. 5 shows the macrographs of the above three alloys at full size after etching with boiling 20 per cent ammonia persulphate solution. It is evident that the presence of cobalt has a considerable influence on the grain size.

Series B.—Brass with 60.34 Cu, 0.64 Co is formed $\alpha + \beta$ constituents. Its fictitious composition (61 per cent) as shown in the microscope is a little higher than the real. Alloy 60.50 Cu, 2.27 Co possesses a structure analogous to the above, but its fictitious composition is even higher, being around 62 per cent. Brass containing 60.48 Cu, 4.81 Co shows but little β , but has a little of a special constituent apparently the same as found in the brass 70.76 Cu, 4.35 Co of Series A (Fig. 6).

Calculating the coefficient of equivalence⁶ for cobalt from these data, disregarding the last sample, which contains a constituent other than the normal solid solutions found in brasses, it is found that the value of t varies between -0.7 and -0.1 .

Macrographs of this series again show that cobalt has a very great influence on the grain size.

Micrographs Figs. 7 and 8 (magnified 74 diameters) show the structure of these alloys.

Series C.—The three alloys with about 55 per cent copper are formed of α and β solutions, none presenting any special constituent, as may be seen in Figs. 9, 10 and 11. But it is apparent that they all present very different fictitious compositions, determination of which will serve for calculating the coefficient of equivalence t for cobalt.

Alloy 55.46 Cu, 0.78 Co has a fictitious composition of

⁶See CHEM. & MET. ENG., vol. 24, p. 177.

TABLE I. COMPOSITION OF COBALT BRASSES INVESTIGATED

No.	Analysis Wished			Analysis Obtained					Shock Tests		
	Cu	Co	Zn	Cu	Co	Zn	Fe	Pb	Total	Angle	Hard- ness
Series A	1	70	1	29	70.20	0.72	28.96	0.07	tr.	99.99	44
	2	70	2	28	70.28	1.94	27.66	0.07	tr.	99.95	76
	3	70	5	25	70.76	4.35	24.79	0.07	tr.	99.97	82
Series B	4	60	1	39	60.34	0.64	38.86	0.07	tr.	99.91	72
	5	60	2	38	60.50	2.27	37.05	0.07	tr.	99.99	71
	6	60	5	35	60.48	4.81	34.62	0.08	tr.	99.99	107
Series C	7	55	1	44	55.46	0.78	43.66	0.08	tr.	99.98	138
	8	55	2	43	55.63	2.42	41.86	0.07	tr.	99.98	104
	9	55	3	40	55.46	4.98	39.45	0.08	tr.	99.97	125

each series from 0.5 to 5 per cent. In reality the figure given for cobalt represents the sum of nickel plus cobalt, since the composition of the cobalt used in making up the alloys was 93.13 Co, 0.78 Ni, 0.90 Si, 0.17 Cu, 1.61 Fe.

MICROGRAPHIC AND MACROGRAPHIC EXAMINATION

Series A.—The alloy 70.2 Cu, 0.72 Co is formed by a single solid solution in relatively coarse crystals. It can be admitted *a priori* that it is the α solution of brasses. Alloy 70.28 Cu, 1.94 Co is also formed of a single solid solution; but with the same rate of cooling, the crystals are of much smaller dimensions than the former. Alloy 70.76 Cu, 4.35 Co (Fig. 6) contains two constituents, a solid solution whose elements are much smaller than either of the preceding, and a star-like special constituent which looks very much like one of the solid solutions in the binary copper: cobalt system.

⁵CHEM. & MET. ENG., vol. 24, p. 261.

FIG. 5. MACROGRAPHS OF COBALT BRASSES

Fig. 6. 70.76 Cu, 4.35 Co brass.

FIG. 6 TO 8 (ALL $\times 55$)
Fig. 7. 60.5 Cu, 2.27 Co brass

Fig. 8. 60.5 Cu, 4.81 Co brass.

56.5 Cu, that of the alloy 55.63 Cu, 2.42 Co is 59 Cu, and that of the alloy 55.46 Cu, 4.98 Co is approximately 61 Cu. The coefficient of equivalence calculated from these values is respectively

$$t = -1.5, t = -1.4, t = -0.9.$$

Macrographs again show clearly that the grains become smaller as cobalt increases.

It is to be noted that there is an important variation in the coefficient of equivalence of cobalt for variations in the composition of the alloy under examination, the values of t varying between -0.1 and -1.5 . It would seem that the nearer the alloy approaches the point where the special constituent appears—i.e., to the

The tests for the mechanical properties of cobalt brasses have been made under conditions similar to those used for the nickel brasses,⁷ only cast samples being tested. The results obtained are tabulated in Table II.

The results are often irregular (notably alloy No. 2 under tension) but some interesting conclusions may be drawn.

Thus: Series C (alloys Nos. 7, 8 and 9) clearly show the relation between the fictitious composition and the

8	55.63	2.42	57,700	32.0	38.9	11.2
9	55.46	4.98	63,400	39.0	54.6	14.0

saturation limit in cobalt of the α and β constituents—the smaller the coefficient. It is worthy of remark that cobalt is the only element yet known which possesses a variable coefficient of equivalence.

mechanical properties. The strength and the elongation increase simultaneously.

Alloy No. 6 (high-cobalt) shows a very appreciable decrease in elongation, a fact which is not observed for alloy No. 3, although both these products contain a little of a special constituent.

MAGNETISM AND TRANSITION POINTS

Determinations by a magnetized needle indicate that brasses containing 0.70 per cent cobalt are non-magnetic, but brasses with 2, 4 and 5 per cent cobalt are clearly

⁷See CHEM. & MET. ENG., vol. 24, p. 261.

Fig. 9. 55.4 Cu, 0.78 Co brass.

FIGS. 9 TO 11 (ALL $\times 55$)
Fig. 10. 55.6 Cu, 2.42 Co brass.

Fig. 11. 55.46 Cu, 4.98 Co brass.

magnetic, the magnetism increasing with the increase in cobalt.

Transformation points have been determined with a Saladin-Le Chatelier apparatus and the results tabulated in Table III. The tests show that:

Cobalt brasses have transformation points which correspond approximately to those of ordinary brasses having real compositions equal to the fictitious compositions of the alloys considered.

Alloys having equal fictitious compositions have different transformation points, since the presence of cobalt slightly raises these temperatures. This is brought out by comparing the results on samples Nos. 2 and 5.

Microscopic observation failed to resolve the β constituent in any of the cobalt brasses studied.

CONCLUSIONS

Cobalt enters into solid solution in one or both of the normal constituents of the Cu:Zn alloys and creates a

fictitious composition which is greater than the real composition.

The coefficient of equivalence of cobalt varies between wide limits, from -0.1 to -1.5 , whereas that of nickel⁸ is approximately -1.3 .

A special constituent is isolated as the cobalt content increases, and the more readily for brasses of lower copper content. Only traces of this constituent were noted in the samples studied, so that it can be said that the alloy is not thereby altered extensively. It is to be noted, however, that the alloy 60 Cu, 4.8 Co has a considerably decreased elongation and resiliency.

Copper:cobalt solutions are much less extensive than those of copper:nickel.

Additions of cobalt are not of great industrial importance in the manufacture of brasses.

The rôle of cobalt approaches that of nickel in brasses, although these two metals have completely different effects in steels.

⁸See CHEM. & MET. ENG., vol. 24, p. 178.

The Manufacture of Nitric Acid

AT A MEETING of the Delaware Section, American Chemical Society, held Wednesday evening, Feb. 23, an address on "The Manufacture of Nitric Acid" was given by F. C. Zeisberg, manager of the elementary process section, E. I. du Pont de Nemours & Co.

EARLY DEVELOPMENTS

In 778 A.D. Geber, an Arabian alchemist, obtained *aqua dissolutiva* from saltpeter, copper sulphate and alum. Because of its solvent properties, nitric acid was made on a semi-commercial scale even during the Middle Ages. Illustrations of the crude forms of apparatus will be found in a work by Lazarus Ercker published in 1580. The substitution of cast iron for earthenware retorts began between 1720 and 1759 and Chilean nitrate was first used as raw material in 1830. Until quite recently the horizontal cylindrical type of retort was extensively used in this country. The cast-iron cylinders were mounted in pairs in brick settings and the ends were closed with cast-iron plates or, in some cases, brickwork. A charge of 3,000 lb. of sodium nitrate was considered large.

In 1912 the du Pont company first installed the vertical or pot retorts.

REACTIONS INVOLVED IN MODERN PROCESS

Two equations are commonly used to express the formation of nitric acid from sodium nitrate and sulphuric acid:

It will be noticed that reaction 1 requires only one-half as much sulphuric acid as the second reaction. However, the saving in acid is offset by the fact that the residue left in the retort has such a high melting point as to make its removal a difficult and troublesome operation.

Experience has shown that an $\text{H}_2\text{SO}_4:\text{NaNO}_3$ ratio of 1:1 by weight gives the best results. The cake formed in this case contains both Na_2SO_4 and NaHSO_4 , and consequently has a melting point lower than that of either component. These relations may be summarized as follows:

	Ratio $\text{H}_2\text{SO}_4:\text{NaNO}_3$		Melting Point
	By Weight	Molar	of Residue, Deg. C.
Reaction 1.....	0.576	0.5	888
Reaction 2.....	1.15	1	186
Actual charging ratio.....	1	0.87	± 178

For successful operation the 1:1 ratio should be adhered to rather closely. A higher ratio causes the phenomenon of "pumping" (which if serious may drive part of the charge into the condenser) and increases the sulphuric acid cost but gives a stronger distillate and lower repair costs. On the other hand, a low ratio saves sulphuric acid, but repair costs are higher and the distillate is weaker due to decomposition of nitric acid at the high temperature necessary in this case.

RAW MATERIALS

Chilean nitrate as purchased has an average composition of 2.15 per cent H_2O , 1.70 per cent NaCl and 94.10 per cent NaNO_3 . It is dried to below 0.5 per cent H_2O so as to avoid unnecessary dilution of the distillate. The size of the nitrate particles is important, since very fine material tends to form cakes in the retort. These may break up later and react with almost explosive violence, or they may remain unacted upon and thus lower the yield.

Sulphuric acid recovered from spent mixed acid used for nitrating is found to work well, no matter how black and muddy. Even tank bottoms containing 30 to 40 per cent ferric sulphate have been used successfully. The strength of the acid is important, however, since very strong acid will dehydrate the HNO_3 according to the reaction:

The NO_2 passes through the condensers to the absorbers and later the water distills over, diluting the strong distillate. With dry NaNO_3 , 92.5 per cent H_2SO_4 gives the optimum strength of distillate.

DISTILLATION PHENOMENA

Curves plotted from the averaged data of ten runs with charges of 6,500 lb. NaNO_3 show many interesting phenomena. The strength of distillate is a little low at first due to water vapor and nitrosyl chloride, but soon rises to a maximum of about 97 per cent, after

which it falls off gradually. The rate of distillation increases to a prime of 18 lb. per minute about three hours after heat is applied and then decreases regularly. Soon after firing, the charge begins to foam and the foam depth increases until just before the end of the reaction, when the retort is practically full of foam. After reaching this point the foam drops abruptly and this serves as one of the best indications that the reaction is complete.

After the distillation has been in progress for about three hours the mushy charge sets to a solid pumice-like block which gradually melts again. This peculiarity has proved to be a most serious stumbling block for continuous processes which depend upon gravity flow.

The time required for a distillation cycle varies with the charge about as follows:

Charge Sodium Nitrate, Lb.	Single Shift, Hr.	Continuous, Hr.
4,000	7 to 8	...
5,000	9 to 10	...
6,000	10 to 12	...
7,000	12 to 14	12
9,000	Over 14	...

THE MODERN PLANT

A modern nitric acid plant includes: A battery of retorts connected in pairs to condensers provided, as a rule, with bleachers; absorption towers for the recovery of uncondensed vapors; a variety of accessory apparatus such as charging devices for nitrate and acid, storage system for the weak and strong cuts or mixing tanks if mixed acid is to be made.

RETORTS

Vertical cast-iron retorts are usually made with detachable hemispherical bottoms, although a recent bottom design is based upon the catenary of revolution, the theory being that this shape will give maximum strength. The retorts are set in brickwork and are heated directly by coal fires. The life of a retort is from 500 to 600 runs. Occasionally this is exceeded, as in the case of a retort at Repauno, which lasted 1,763 runs. During this time the thickness of the casting was reduced by erosion from 2 in. to about $\frac{1}{4}$ in. Most retorts fail through cracks developed by the heat. Patching prolongs the life about 100 runs.

CONDENSERS

Several types of condensers are in use. The improved Hart condenser consists of one or more stands each containing fourteen inclined 3-in. glass tubes connected to baffled headers so that the vapors make three passes. Each stand offers about 50 sq.ft. of condensing surface. Tube breakage is high—about 100 tubes per retort per year.

The Hough Duriron condenser is very open in construction and offers little resistance to gas flow. When operating intermittently in cold weather, water is likely to become trapped in the condenser and burst it in freezing.

S-bend condensers of 6-in. Duriron or fused silica pipe cooled by trickling water over the outside are very efficient.

A condenser described by F. Moore and J. A. Hall in U. S. Patent 986,846 of March 14, 1911, and used at the Shand plant of the Canadian Explosives Co. on Vancouver Island gives a distillate containing less than 0.1 per cent NO_2 . It consists of a tower containing a

large number of vertical tubes inside of which the condensing water circulates. The condensed acid passes countercurrent to the hot vapors through a packed section at the base of the tower which serves as a bleacher.

ABSORPTION SYSTEM

No condensers were used in the earlier systems, the nitric acid being distilled directly into sulphuric acid. This gives a mixed acid containing nitroso sulphuric acid, which is undesirable for certain nitrations. The first absorption towers using water were built at Hercules, Cal., from sewer tile filled with broken beer bottles. The acid which drained from the bottom of each tower was allowed to flow into a carboy and when this was full, it was carried upstairs by workmen and dumped into the top of the next.

Modern towers are constructed of chemical stoneware, six sections 30 in. in diameter by 30 in. high forming a typical tower. Coke, lump quartz or specially designed stoneware packing may be used to fill the tower. If of the dimensions given, 3,600 3-in. rings would be required. Finding a suitable construction material for the saucer in which the tower rests presents quite a problem. Volvic stone saturated with some bituminous material is only fairly satisfactory. The same may be said of Duriron. The du Pont company has obtained excellent service from Maine granite.

The reaction which takes place in the towers is the reverse of reaction 3. In order to get a strong acid it is necessary to have a series of towers, with water entering at the end of the series and flowing countercurrent to the gases. The acid collecting in each saucer flows to a distributing pot provided with two discharge openings leading to two stoneware pulsometers which operate by compressed air and insure a rapid circulation of acid in the tower. The distributing pots are interconnected so that as acid is formed it flows from one tower to the next toward the strong acid end. Baffles in the pots prevent water from passing through the whole series into the strong acid when the air is shut off from the pulsometers.

STORAGE AND TRANSPORTATION

Very strong nitric acid can be stored in lead-lined tanks, although there is considerable corrosion in the vapor space above the acid. Weak acid is best kept in stoneware pots, these being available in sizes up to 530 gal. Around the plant the acid is handled in pipe lines of chemical ware, glass or Duriron.

At best, however, the problem of handling the pure acid is a troublesome one. Since nitric acid is now used almost exclusively as mixed acid and since this can be handled easily in steel tanks and tank cars, steel circulating tanks are usually provided in which the nitric acid may be mixed with the required amount of sulphuric acid.

As indicated above, transportation of nitric acid is difficult except in the mixed form containing at least 12 to 13 per cent of H_2SO_4 . Glass carboys are used to quite an extent and for short distances chemical ware, glass or Duriron lines are satisfactory. In Germany and Norway, perfectly pure HNO_3 is transported in aluminum containers. Traces of H_2SO_4 , Cl_2 or NO_2 cause rapid corrosion.

YIELDS AND COSTS

From 94 per cent in 1900, the yield rose to 96.8 per cent in 1913 and—in spite of wartime demand for out-

put—to 97.6 per cent in 1918. At present it is nearly 99 per cent. In 1913, the production of 1,000 lb. HNO_3 required 265 lb. of coal and 1.9 men-hr. labor. Corresponding figures for 1918 are 222 lb. and 1.4 men-hr.

The normal cost of producing 100 lb. of nitric acid is distributed as shown in the accompanying table.

NORMAL COST PER 100 LB. HNO_3		
Labor.....	\$0.06	
Repair labor.....	0.06	
Retorts.....	0.08	
Supplies.....	0.05	
Fuel.....	0.03	
Power.....	0.03	
Overhead.....	0.18	
	\$0.49	
Less credit for nitercake.....	0.24	
Cost exclusive of raw materials.....		\$0.25
Sodium nitrate, 145 lb. @ 2.5c.....	\$3.63	
Sulphuric acid, 151 lb. @ 1c.....	1.51	
Cost of raw materials.....		\$5.14
Total cost.....		\$5.39

It will be noted that the raw material cost far exceeds all other items and that, consequently, increasing the yield 1 per cent would have as much effect in decreasing the cost as doubling the life of the retorts. Although similar relations exist in many other chemical processes, they are often lost sight of and much time is wasted in misdirected efforts to diminish costs.

PRODUCTION

Production statistics for the United States are as follows:

Year	HNO_3 Production, Short Tons
1904.....	59,000
1909.....	68,000
1914.....	79,000
1917.....	404,000
1918.....	634,000

Present production is somewhat above that of 1914. Normally the du Pont company makes one-third of the nitric acid produced in this country, but during the war the proportion rose to one-half.

OTHER PROCESSES

The Valentiner vacuum process proved to be a failure commercially. Recently the Buffalo Foundry & Machine Co. has devised a vacuum process which promises to be very efficient. The retort is provided with a powerful agitator and the sulphuric acid is added automatically. In this way foaming is reduced to a minimum in spite of the fact that distillation takes place in a vacuum (maintained by a special pump having a sulphuric acid piston to minimize corrosion). No absorption towers are used, the uncondensed vapors being absorbed in concentrated sulphuric acid which is subsequently used in the retort. As noted above, the continuous process fails owing to the solidification of the charge at one stage.

USES

Peace-time uses include: manufacture of chamber sulphuric acid, aqua regia, nitroglycerine, nitrobenzene, nitrocotton, fulminates and nitrates; pickling of copper, bronze and brass; parting of gold and silver; purification of silver; gilding bronze; photo-engraving; silk dyeing.

In war time it is used in making nitrocotton, nitroglycerine, trinitrotoluene, fulminates, ammonium nitrate and many other compounds.

Progress Report on Superpower Survey

THE Congress, in appropriating for the Geological Survey, June 5, 1920, provided for the survey of power production and distribution in the United States, including the study of methods for the further utilization of water power and the special investigation of the possible economy of fuel, labor and materials resulting from the use in the Boston-Washington industrial region of a comprehensive system for the generation and distribution of electricity to transportation lines and industries.

While the final report has not been completed, a progress report was submitted to the President on Feb. 24 by John Barton Payne, Secretary of the Interior, giving results thus far accomplished, with a brief statement of the scope of the investigation.

ENGINEERING STAFF AND ADVISORY BOARD

An organization was effected under the Geological Survey with offices for the engineering staff in New York City. The engineering staff includes William S. Murray, as chairman; Nathan C. Grover, the chief hydraulic engineer of the United States Geological Survey; Ozni P. Hood, chief mechanical engineer of the Bureau of Mines; Lorin E. Imlay, division engineer for the subjects of power and transmission; Henry W. Butler, division engineer for industries, and Cary T. Hutchinson, division engineer for railroads, with Henry Flood, Jr., engineer-secretary. The engineering staff has been aided by the hearty co-operation of an advisory board of business and professional men, who accepted appointments for this special service. Of this board Prof. Lester P. Breckenridge of Yale is chairman, and the various interests connected with this investigation are represented as follows: Magnus W. Alexander of Boston, representing the National Industrial Conference Board; Edward G. Buckland, vice-president New York, New Haven & Hartford R.R.; Charles L. Edgar, of the Boston Edison Co., representing the National Electric Light Association; Abraham T. Hardin, vice-president New York Central R.R.; Herbert Hoover, representing the mining industry; William Kelley, Lieutenant-Colonel, U. S. A.; Elisha Lee, vice-president Pennsylvania R.R.; Dr. Arthur D. Little of Boston, representing the electrochemical and byproducts industries; James H. McGraw, president McGraw-Hill Co., Inc., representing the technical press; John H. Pardee of New York, representing the American Electric Railway Association; Henry Cleveland Perkins of Washington, representing the mining industry, and Matthew S. Sloan, of the Brooklyn Edison Co., representing the National Electric Light Association.

Having in mind the object of the Superpower Survey, viz.: (1) allocation and amount of waste in labor, coal and other materials, due to the improper form of power generation and distribution within the Boston-Washington zone, and (2) recommendations regarding a regional power system by means of which these wastes may be eliminated, the superpower report naturally divides itself into three divisions: (1) Physical, (2) Legal, and (3) Financial.

PHYSICAL ASPECTS OF SURVEY

With regard to the physical aspect, the investigation has been concerned with the power necessary to (a)

railroads, (b) industries, (c) utilities, and (d) a system of centralized electric generation and transmission to supply their power requirements up to and including 1930.

RAILROADS

There are twenty class 1 railways included in the superpower zone. These are divided as follows: First track, 14,500 miles; second track, 6,500 miles; total trackage (including yards and sidings) 36,000 miles. There are a total of 10,000 steam locomotives, of which 44 per cent are freight, 29 per cent passenger and 27 per cent switching. The total annual railroad coal consumption for 1919 was 19,000,000 tons. Apparently one-third of this mileage can be economically electrified, including the greater part of double track mileage. Due to lack of traffic density upon the branch lines, these cannot be profitably electrified. This 33 per cent of mileage will carry more than 50 per cent of the traffic and by preferential arrangement of routes probably 60 per cent of the total traffic could be put over this mileage. Through the electrification of this mileage a fuel saving of 6,000,000 tons, or \$40,000,000 per annum, would be effected. Added to this saving will be \$50,000,000 annually as a difference in favor of electric versus steam engine repairs and maintenance.

The total unit cost of electrification will be approximately \$40,000 per mile of main line track, which with 12,600 miles to be electrified would cost \$500,000,000. In addition, yard and siding trackage would call for \$300,000,000, or a total of \$800,000,000. This sum will cover the necessary construction and equipment for the railways beginning with the electric substations and with the driving wheel of their electric motive power. The electrification outlined will displace approximately 7,000 steam locomotives, which at salvage value of \$22,500 each will credit the electrification estimate with approximately \$150,000,000, leaving a net investment of \$650,000,000 which taken in connection with the aforementioned savings of \$90,000,000 per annum would return approximately 14 per cent on the investment.

INDUSTRIES

There are approximately 50,000 industrial plants in the zone which either purchase or generate power. The Bureau of the Census is at present compiling the statistics of the 1919 Census of Manufactures. It is heartily co-operating with the Superpower Survey and will prepare, on a form made up by this Survey, the power and fuel statistics for the superpower zone, which will show the power and fuel requirements in the thirty-six major industries in the following classification of plants: Plants which do not use any power, plants using only steam power, plants purchasing electric power, plants not in these classes. In addition the plants will be classified as to size.

As soon as the tabulations are completed by the Bureau of the Census, the Survey in conjunction with experts in the various industries, will analyze and ascertain what possible fuel savings could have been made by the superpower system in 1919. From the data at hand, a saving of between six and eight million tons of coal is indicated.

In the anthracite coal mines of Pennsylvania, by means of electrification and the supply of superpower, a conservative estimate based on actual tests shows a saving of 6,500,000 gross tons of anthracite. The Survey is at present preparing estimates on the cost of completely electrifying the anthracite mines.

The data required of the Industrial Division will be ready by May 1, for assembly in its final form.

UTILITIES

A large saving of coal can be effected through the more efficient generation of power by the new superpower stations. The Survey finds that the average rate of coal consumption for present central station output is $2\frac{3}{4}$ lb. per kw.-hr. Power can be produced in the superpower system at an average rate of $1\frac{3}{4}$ lb. per kw.-hr. The present central station output of coal-generated power within the zone is 8,000,000,000 kw.-hr. Therefore 1 lb. saved per kw.-hr. will conserve 4,000,000 tons of coal annually.

ELECTRIC POWER GENERATION AND TRANSMISSION

The location of the large superpower stations and their attendant transmission lines is related to the establishment of load centers throughout the superpower zone to which power will be transmitted from them at minimum distance.

To date it is indicated that about twenty load centers will be established. Early in March sufficient data will be at hand to establish these load centers, after which the location of new superpower stations and their interlinking transmission systems can be promptly determined within the zone.

The development of power outside of but for transmission to the zone is being most carefully considered, having relation to the St. Lawrence River, other hydroelectric powers and the bituminous coal mines. It has been agreed among the experts of the country that 250,000 volts will be an acceptable voltage for the transmission of power from distances greater than 200 miles and at about half that value for the zone itself.

A conference with the coal authorities indicates that a fair figure to take for the average price of coal during the period 1919 was \$2.90 per ton at the mine, and during the period from that date to 1930, \$3.50 per ton.

With regard to water power for the zone, a summation of the possible outputs from the Potomac, Susquehanna, Delaware, St. Lawrence (American rights), Raquette and the Adirondack powers indicate that for an average year there will be available 12,000,000,000 kw.-hr., and for a minimum year 8,360,000,000 kw.-hr., the plant capacity being 2,300,000 kw. to furnish this amount of energy. It is of interest at this point to state that in 1930 the total power requirement in the superpower zone indicated by projected growth curves will be 48,000,000,000 kw.-hr., of which amount the superpower system could supply 36,000,000,000 kw.-hr. This, therefore, indicates that the water-power supply can be but from 20 to 25 per cent of the total. This fact forces the conclusion that most careful consideration must be given to the efficient development of power from coal.

The report will contain a chronology indicating time and location of superpower stations to be constructed in the order of their requirement, giving savings to be effected as their serial installation is made.

Through the unusual co-operation of the public utilities, the railways and the industries, the completion of the work will be, after May 1, substantially a matter of computation and tabulation.

The legislative and financial aspects of the survey include many important problems such as the formation of a corporation and the method of financing it. These will be considered in detail in the final report which is expected to be ready by June 30, 1921.

Current Events

in the Chemical and Metallurgical Industries

Plans for Annual Meeting of T.A.P.P.I.

Several reports of unusual interest and value will be presented at the annual meeting of the Technical Association of the Pulp and Paper Industry which opens at the Waldorf-Astoria Hotel, New York, on Tuesday, April 12.

PULVERIZED FUEL AND STEAM ECONOMY

The committee on heat, light and power is planning a symposium on powdered fuel and steam economy. The leading paper in the symposium will deal with certain definite conditions in steam plants, and discussion will afterward be centered on individual problems in different mills. The chairman of this committee is Howard S. Taylor, of the Management Engineering & Development Co., City National Bank Building, Dayton, Ohio.

An illustrated paper on waterwheel testing, based on the results of twenty years' experience in testing waterwheels in the grinder rooms of mills in the United States and Canada, will be presented by a New England expert who has developed a simple scheme of showing results and indicating methods of operating to insure maximum efficiency.

REPORT ON GROUNDWOOD PROCESS

The committee on groundwood, or mechanical pulp, headed by W. A. Munro, of the Wisconsin River Paper & Pulp Co., has conducted a searching investigation into the merits of the Hall process of grinding wood, and a most suggestive and valuable report has been compiled from communications made by users or licensees of the process. The subject has been investigated from three angles—that of the grinder room, of the paper machine room and of the press-room. The resistance of paper made from Hall process pulp to strain in turning the angle bars of big newspaper printing presses forms part of the study, the committee being in possession of several interesting letters from the press-rooms of the larger dailies.

PLANS FOR DYE INVESTIGATION

Ross Campbell, department of technical control, American Writing Paper Co., Holyoke, Mass., has been named by President Hatch to succeed Dr. Otto Kress as chairman of the committee on dyestuffs. One of the first tasks of this committee will be to check up the chapter on dyes in the vocational education textbook. The dyestuffs committee has some ambitious plans for reporting on the performance of different dyes under different conditions, their peculiarities, different combinations in which special dyes should or should not be used, etc.

INDIVIDUAL PAPERS IN PROSPECT

Among contributions to the session on scientific papers, one is promised from the Forest Products Laboratory dealing with a new method of pulping in which the cooking time is shortened by preliminary impregnation. A number of individual papers will be presented on such subjects as methods of drying paper on paper machines, the testing of crude rosin, measuring moisture in chips for cooking, facts and figures on power required for paper machines, etc.

Army Needs Commissioned Personnel

Competitive examinations will be held April 25 to fill 2,585 vacancies in the commissioned personnel of the army. There is a particular desire at this time to obtain as many technical men as possible. There are more than 4,000 vacancies in the army, but only a portion of them will be filled at this time. Among the vacancies to be filled at this examination are thirty-two in the Chemical Warfare Service.

Distribution of Industrial Stocks

A recent issue of the *Boston News Bureau* gives in tabular form a three-year comparison of the total number of stockholders in leading industrial firms. The data given in regard to the following chemical and metallurgical organizations show how these "partners" of big business have increased in number in recent years.

	—Number of Stockholders—

* Total of all stockholders. † Exclusive of over 10,000 employees buying stock on installment plan. ‡ Approximately.

In many organizations a substantial percentage of the stock is now owned by employees. Thus, the United States Steel Corporation reports a total of 160,300 stockholders as of Jan. 31, 1921, 66,506 being employees who own stock outright. This does not include a large number of employees who are buying stock on the subscription plan.

Civil Service Examinations

Until further notice applications will be received by the United States Civil Service Commission on Form 1312 for the positions of: Associate physicist qualified in physical metallurgy, at a salary ranging from \$2,000 to \$2,800 a year; assistant physicist qualified in physical metallurgy, at a salary ranging from \$1,400 to \$1,800 a year. Vacancies in the Bureau of Standards, for duty at Washington, D. C., or elsewhere, will be filled from this examination.

Gala Night Planned at Chemists Club

The Chemists Club of New York City is getting ready for a gala night which will fall on March 17—St. Patrick's day. The purpose of this is by no means to establish the greatest of all snake charmers as the patron saint of chemists. There is no legend in connection with the great Scotchman, who went to Ireland and did *not* settle down in Belfast or Londonderry, to indicate that he had any interest whatever in the philosophy of matter. It is the tenth anniversary of the date in 1911 when the club moved into its present splendid quarters, and the trustees have planned a celebration.

The meeting is restricted to members of the club, and begins with a dinner without speeches at which the following gentlemen, made honorary members at the last general meeting, or, in the event of their inability to be present, duly accredited representatives from the embassies of their governments, will be the guests:

Giacomo Cimician, of Italy; Henri Louis Le Chatelier, of France; John Uri Lloyd, of Cincinnati, Ohio; William Henry Nichols, of New York, N. Y.; Edgar Fahs Smith, of Philadelphia, Pa.; Ernest Solvay, of Belgium; Sir Edward Thorpe, of England; Edward Weston, of Newark, N. J.

After the dinner honorary membership will be formally conferred upon the gentlemen, following which there will be an address by Irving Langmuir and Jacques Loeb on subjects not yet specifically announced, but relating to developments in chemistry, from the standpoints of pure science and biology. This will take place in Rumford Hall, and after the meeting there will be a reception to the new members and their representatives in the club parlors.

The occasion promises to be memorable and to contribute a note in the history of chemistry in America.

Chicago Section, A.C.S., Meeting

The Chicago Section of the American Chemical Society met at the City Club Feb. 18 for dinner, followed by a business meeting. Several amendments to the constitution were passed by unanimous vote of the members present. The principal one of these provided for changing the name of the *Chicago Chemical Bulletin* to the *Chemical Bulletin*. While the latter has headed the organ of the Western sections for some time, this action officially confirmed the name.

The address of the evening was delivered by Dr. L. V. Redman, who spoke on phenol condensation products, treating the subject from a practical standpoint. He reviewed the history of the development of synthetic resins from the work of Bayer in 1873. Smith of England took out the first patents in 1899, followed by Luft in Austria. Story, Claypool and Baekeland carried the work down to present developments. He spoke highly of Dr. Baekeland's work in building up a large commercial organic chemical institution which turns out excellent products. The history and details of synthetic resin production are confined almost wholly to patent literature.

He outlined the processes of manufacture now in vogue and exhibited many samples where the resins are useful in the arts. The modern automobile, airplane and other electrical machinery with comparatively high tension require insulations made from these resins compounded with wood flour, asbestos, cambric, etc.

The unusually large attendance of the second largest section at this meeting was in the nature of an ovation to the speaker. Redmanol cigar holders were served as favors at the dinner.

Production of Ore in Soviet Russia

From official Russian sources it appears that the mines of Kriwoi-Rog, which before the war contributed about three-quarters of the whole Russian iron production, have in the last year produced nothing.

The production of the copper mines has dwindled down to insignificance. The production of lead is 10 to 25 per cent that of the pre-war output.

The total of iron-ore production in 1920 was one-tenth of the quantities expected. In the Ural districts only 9,000 workmen, instead of 27,000 before the war, are employed.

Central Leather Co. Report

The annual report of the Central Leather Co. presents a typical case of the extraordinary depreciations in inventories which had such disastrous effects upon the leather industry during 1920. The report shows a loss, after charges and taxes, of \$22,428,214. This compares with a surplus of \$14,288,481 in 1919, which was equivalent after deducting preferred dividends to \$30.11 a share on common. Conditions during 1920 are summarized in the report as follows:

Distinct advance in price of raw material and finished leather, which was resumed in December, 1919, continued and increased during first two months of 1920. Our sales and advance orders in January and February of last year for active domestic consumption exceeded our supply and our production for some months in advance and raw material was therefore provided.

The abnormally severe winter, almost complete breakdown of transportation system of the country, delays in delivery and cancellation of orders with cessation of retail buying, all worked to produce by early summer a condition of almost complete stagnation in our industry, in common with or possibly beyond that in others. This situation made impossible a liquidation so obviously advisable.

Confronted by this condition—which, in short, resulted in a precipitate fall in price of raw material and practically no market for finished products—the management decided on the drastic policy of almost complete closing of its tanneries. From May until November we reduced purchases of hides to a minimum and liquidated inventories where possible. Not until November, when prices had reached or passed pre-war levels, did we again purchase hides in quantity. During this period the prices of finished products declined on a very restricted market. Inventories of finished products—necessarily large in a company of our size—have been marked down successively to meet the market declines. Result has been an inventory loss on leather sold and unsold, which has absorbed a very great part of the surplus. On Dec. 31, 1920, this company had practically no commitments for purchase of raw materials.

Directory of Petroleum Refineries Issued

A complete directory of petroleum refineries in the United States has just been issued by the United States Bureau of Mines. The report, compiled by H. F. Mason, petroleum economist, states that there are 415 completed refineries in the country, as compared with 373 in 1920. In addition, 44 refineries are in process of construction. The present daily capacity of all refineries is 1,888,800 bbl. of oil, as against a daily capacity of 1,530,565 bbl. in 1920. Texas, with 70 refineries, has the largest number of plants now in operation. Oklahoma has 68, Pennsylvania 51 and California 39 operating refineries. The daily capacity of the Texas refineries now operating is 330,800 bbl.; that of the California refineries is 312,700 bbl.; of the Oklahoma refineries, 248,050 bbl.; while New Jersey, with only 7 refineries operating, has a daily capacity of 215,500 bbl. The report contains data regarding the capacity and type of each plant listed as well as information as to whether at present in operation.

Copies of the report may be had by applying to the Director of the Bureau of Mines, Washington, D. C.

Copper Specifications Submitted for Approval

The American Society for Testing Materials has submitted the following copper specifications to the American Engineering Standards Committee for approval:

Specifications for soft or annealed copper wire (B3-15).

Specifications for Lake copper wire bars, cakes, slabs, billets, ingots and ingot bars (B4-13).

Specifications for electrolytic copper wire bars, cakes, slabs, billets, ingots and ingot bars (B5-13).

Methods for battery assay of copper (B34-20).

The committee (at 29 West 39th St., New York City) would be very glad to learn of the extent to which these specifications are made use of, and to receive any other information regarding the specifications in meeting the needs of the industry.

Petroleum Production of the World for 1920

The estimated world's production of petroleum in 1920 is 688,474,251 bbl., against 554,505,048 bbl. in 1919, according to figures assembled by the American Petroleum Institute. This represents a gain of 133,969,203 bbl., or 24.2 per cent.

Of the total production in 1920 the United States supplied 443,402,000 bbl., or 64.4 per cent. Mexico supplied 159,800,000 bbl. (based on exports of that amount plus production marketed at home), or 23.2 per cent of the world's output.

By far the greater gains were made by the United States and Mexico. United States production increased from 377,719,000 bbl. in 1919 to 443,402,000 bbl. in 1920, a gain of 65,683,000 bbl., or 17.4 per cent. Mexico increased from 87,072,954 bbl. to 159,800,000 bbl., a gain of 72,727,046 bbl., or 83.5 per cent.

The estimated production by countries follows:

	1920	1919
United States.....	443,402,000	377,719,000
Mexico.....	159,800,000	87,072,954
Russia.....	30,000,000	34,284,000
Dutch East Indies.....	16,000,000	15,780,000
India.....	8,500,000	8,453,800
Rumania.....	7,406,318	6,517,748
Persia.....	6,604,734	6,289,812
Galicia.....	6,000,000	6,255,000
Peru.....	2,790,000	2,561,000
Japan and Formosa.....	2,213,083	2,120,500
Trinidad.....	1,628,637	2,780,000
Argentina.....	1,366,926	1,504,300
Egypt.....	1,089,213	1,662,184
France.....	700,000	
Venezuela.....	500,000	321,396
Canada.....	220,000	220,100
Germany.....	215,340	925,000
Italy.....	38,000	38,254
Total.....	688,474,251	554,505,048

1921 Convention and Exhibition, American Society for Steel Treating

The third annual convention and exhibition of the American Society for Steel Treating will be held during the week of Sept. 19-24 at Indianapolis.

The Manufacturers' Building, on the State Fair Grounds, will be used for exhibits. It is 360 ft. in length, by 220 ft. in width; the central section of this building, measuring 240 x 100 ft., is known as the "Sunken Garden," and is 20 in. below the level of the surrounding floor space. The booths along the north wall are to be used for the live exhibits and are supplied with gas and compressed air, while arrangements have also been made for the exhibitors who require heavy electrical current to be on the promenade on the same side of the building.

Meetings are to be held in the Women's Building, located about 400 ft. from the exhibition hall, where there will be available three or more large meeting rooms.

The Indianapolis chapter of the Society is actively engaged in making comprehensive plans to insure the success of the project.

Peruvian Centennial Expositions

This year the Peruvian Government will celebrate the centennial of Peruvian independence, and approximately \$3,000,000 has been voted for this purpose. In connection with the centennial it has been arranged to hold an exhibit of manufactures of other countries and to this end the Peruvian Government has granted concessions to the Peruvian Centennial Exhibits Co., 42 Broadway, New York, and to A. Smeraldi, of Lima, Peru. Information relative to allocation of space and rental charges can be obtained from them.

The buildings in which the two expositions are to be held will very probably be centrally located in the city of Lima and the expositions will undoubtedly be of great interest to consumers and merchants throughout Peru.

British Embargo on Fertilizers

The British Board of Trade has prohibited the exportation of ammonium sulphate, superphosphate, lime, basic slag, and compound fertilizers containing any of these products. This embargo is made under the fertilizer act, 1920, and has been in effect since February 7, 1921.

Book Reviews

FUEL OIL IN INDUSTRY. By Stephen O. Andros. 244 pp. Chicago: The Shaw Publishing Co. Price, \$3.75.

This is an exposition of the qualities of fuel oil and methods of testing, storing and burning it, together with a description of its application to domestic and industrial furnaces. The book gives a concise and informative account of present-day American practice, and hence fills a gap which has existed in the literature of fuels; it is a satisfactory treatise and merits a good reception.

There are some evidences of haste in the preparation of the manuscript of the book for publication and certain of the chemical considerations are in need of revision, but the author undoubtedly will correct these minor defects in the second printing. It also may be pointed out here that, from the standpoint of the engineer, it would be desirable to give more attention to the subject of the function of oil burners in the operation of furnaces. Some one has said that "a properly designed oil furnace is in reality a combination of a gas producer and a furnace," and that "progress has been slow in the efficient use of oil fuel because more is not known about gas producers." The reviewer recently has had occasion to study the practices in heat-treatment and it is clear that there is a prevailing lack of appreciation of the differences between "burning oil," "making heat" and "properly applying heat to obtain a uniformly heated product." It seems to the reviewer that progress in the economical use of oil fuel has been retarded principally by improper furnace design and operation. Generally speaking, the various method of burning oil are similar, based upon the same principles, and learned easily.

W. A. HAMOR.

* * *

THE JOURNAL OF THE INSTITUTE OF METALS, Vol. XXIV. Edited by G. Shaw Scott, Secretary of the Institute of Metals, 36 Victoria St., London, S. W. 1. Price 31s. 6d. net.

This second volume for 1920 contains about 550 pages of text, printed and edited in the usual excellent style. It contains the papers read before the meeting held in the middle of September, together with 100 pages devoted to abstracts of current literature on non-ferrous metallurgy. In timely publication it may well set an example to American societies.

Perhaps the contribution which has attracted most attention and drawn forth the most discussion is that by Miss Elam and Prof. Carpenter on Recrystallization, a paper which was abstracted in this journal on page 224 of the issue for Feb. 2. Another important paper discussing gases contained in brass (by Messrs. Banford and Ballard) was abstracted in this journal for Jan. 19, 1921, page 132. Other papers of interest to metallurgists controlling manufacturing operations set forth various phases of brass manufacture, the constitution of bearing metals and defects in admiralty bronze. For those more interested in research work and in theoretical metallurgy, Miss Bingham of the National Physical Laboratory has contributed a notable article on the allotropy of zinc, while D. Hanson and Miss Gayler have written an extended paper on "The Constitution of the Alloys of Aluminum and Magnesium." The latter contribution is a part of an extended research undertaken by the National Physical Laboratory during the war into the nature of aluminum alloys. Doubtless further results of this painstaking investigation will be published in due time.

This volume also contains the text of the 1920 May lecture delivered by Dr. Carl A. F. Benedicks, on "The Recent Progress in Thermo-electricity." Nearly all of the work as done by Prof. Benedicks and his associates has been published in detail in various physical journals, but in the present instance he collects the main arguments in words not too technical, only alluding briefly to the numerous necessary precautions. Altogether this makes a very interest-

ing account of his brilliant experimental demonstration that thermo-electric currents occur in strictly homogeneous metals—even liquid mercury—as a function of the temperature distribution only, currents of the same magnitude as those of the Seebeck effect. The wide application of thermo-electric pyrometers for engineering work arouses interest in the possible practical uses of these investigations.

A considerable portion of the text is descriptive of work which has gone forward at the National Physical Laboratory, the British counterpart of our Bureau of Standards. Naturally one would expect an extremely high class of work from such an institution, but the quality of the other papers published in the volume does not suffer in the least by comparison. A further point of note is that no less than three of the eleven papers were written either in whole or in large part by women. Evidently the metallurgiste has arrived.

E. E. THUM.

Personal

HOWARD C. ARNOLD, well known in ceramic circles, has recently joined the staff of Arthur D. Little, Inc., Cambridge, Mass. After the war Mr. Arnold studied optical glass at the Bureau of Mines for a short time, and then became chief chemist and plant manager of B. F. Drakenfeld & Co., New York City, where he was chiefly concerned in developing ceramic materials, especially the coloring oxides.

CYRUS E. FRYE has been elected president of the Lincoln Paper Mills Corporation, Elkhart, Ind., to succeed Edward B. Zigler, deceased. Mr. Frye has been in active management of the company for the past year.

ARTHUR L. TUTTLE, who directed the building of one of the largest fertilizer plants at Atlanta for the Tennessee Copper & Chemical Corporation, has returned to New York headquarters.

SAMUEL WANDER, general manager of S. Wander & Sons, New York, has returned to the city after a month's absence at Palm Beach and Miami, Fla., and in Cuba.

Obituary

DANIEL BAUGH, president of Baugh & Sons Co., Philadelphia, manufacturer of animal oils and fertilizers, died on Feb. 28, at Palm Beach, Fla. Mr. Baugh was eighty-five years old and well known in the philanthropic, chemical and commercial circles of Philadelphia.

ROBERT HOLBROOK, chief chemist of the Victor Chemical Works at Chicago, Ill., died at Los Angeles, Cal., on Feb. 11, at the age of thirty-six. He had been in failing health for the past two years and had gone to California to recuperate. He was a graduate of the University of Michigan (1906), a member of the American Chemical Society and the Chicago Chemists' Club, and was recognized as an authority on phosphoric acid and allied products.

WILLIAM A. JONES, president of Richards & Co., manufacturer of Zapon pyroxylin products, died on Friday, Feb. 18, at his home in Tuckahoe, N. Y. Following his graduation at Hillsboro, N. C., he studied under Prof. Ira Remsen at Johns Hopkins. After receiving his doctor's degree, he became associated with Commodore Leonard Richards, who at the time was operating one of the pioneer pyroxylin works, the Boston Artificial Leather Co., which was subsequently reorganized and moved to Stamford, Conn., under the firm name of Richards & Co., and in 1918 taken into the Atlas Powder Co. organization. Dr. Jones was known as the "Dean of the Industry," through his lifelong devotion to the chemistry of pyroxylin solutions and artificial leather. His wife and sister survive him.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, March 4, 1921.

Intermittent periods of dullness and activity characterized trading in the chemical market during the past week. In spite of recent pessimism, however, it is generally agreed that February was the brightest month since the present period of depression. Margins of profit have not been comparable with those of 1920, but the volume of business has been in some cases greater than that of February of last year. The characteristic point of difference between the two periods is the lack of repeated turnover which was so general a year ago. The market this year seems to have been based on business direct from manufacturer or importer to consumer, while business last year was carried on through a multiplicity of intermediate hands, each of whom took his profit from every individual transaction.

Sentiment is steadily improving and while price trends are still downward on account of competitive selling of foreign goods, it is generally conceded that the next three months will see business on a sound normal basis again. The readjustment of quotations recently made by manufacturers has not been altered to an appreciable degree. Consumers are still operating cautiously with the idea that more attractive prices may be established later on. There are three great factors, however, hindering any noticeable readjustments and these are the high freight rates, high coal prices and high wages. Other factors are contributors to the general result, but the removal of the three named would open the way for permanent progress and disperse any doubts which still cling to the chemical industry. Second hands who refuse to take their losses on old contracts know there is a potential shortage of goods which would develop into a real shortage with any noted improvement in trade conditions.

Light *soda ash* held quite steady on the spot market and while an isolated car was occasionally sold at a price concession, most dealers held single bags at \$2.05@ \$2.10 per 100 lb. Barrels were quoted by dealers at \$2.20@ \$2.25. The absence of any live export business left the price for resale ash in double bags at \$2.10. Producers' views are unchanged at \$1.72½ per 100 lb., basis 48 per cent, f.o.b. works, in single bags for prompt and future shipments. *Prussiate of soda* has attracted some interest, mainly because the market was flexible, and prices have receded under spirited competition from holders of imported goods. Spot prices have shown irregular weakness, with foreign material offered down to 14½c. per lb., with a possibility of shading on firm business. Forward shipments were offered at 14c. per lb.

Standard 99 per cent *copper sulphate*, large crystals, could be purchased at lower prices from producers and business is reported in carlots on a basis of 5½c. per lb. The small crystals, 98½-99 per cent, were offered by first hands at 5¼c. per lb. Smaller quantities of both varieties commanded a slight premium depending upon the size of the order. The lower prices in this commodity are directly the result of the decline in the course of production which is made possible through lower copper quotations. While the South American inquiry is practically at a standstill at the present time, a demand has developed for shipment to Europe, particularly to Italy and France and other grape-growing countries. European buyers who should have bought their requirements a few months ago have stayed out of the market as long as they could with the idea of getting material at a lower figure. The approach of the season for insecticide users has stimulated this foreign inquiry. Germany is competing for this business, but it seems that American sulphate is far superior and holds the preference.

Resale lots of domestic *caustic potash*, 88-92 per cent KOH, were on the market at prices ranging from 10@11c. per lb. Large quantities of this material have been returned from abroad during the past few months and these

are responsible for the relatively low prices prevailing. Large producers of *chlorate of potash* are asking 15c. per lb. for the domestic quality for prompt shipment from works. Importations of various grades are on the market at prices ranging from 8c. per lb. upward, depending upon the seller. Most of this material came from Germany and was manufactured during the war. The quality in many cases has been so irregular that consumers have not shown any unusual interest in the product, regardless of the comparatively low prices quoted.

Small lots of *bichromate of soda*, standard brand, were heard from 8@8½c. per lb. Transactions were reported at 8@8¼c. Buyers are only taking small lots at intervals and show little disposition to operate in any large way for prompt and future shipments. Resale offerings of this material do not appear too plentiful, but there is enough competition among second hands to keep prices moderately irregular. *Bleaching powder* has been sold quite freely to paper mills and bleacheries on the basis of 2½c. per lb., f.o.b. works, in large drums. Importers are meeting this figure with offerings of foreign bleach and have been quite successful in disposing of large quantities over the year.

Resellers of spot *carbon tetrachloride* are quoting the market as low as 10c. per lb. Producers are quoting up to 12c. Stocks in second hands are not large. Technical *magnesium sulphate* is very scarce on the spot, with nominal quotations around \$1.70 per 100 lb. Arrivals are quoted around 1¼c. per lb. Prices on *ammonia alum* have been reduced by leading manufacturers, who are quoting on a basis of 4¼@4½c. per lb. for the lump variety. Business has been done in a limited volume only. Prices were recently reduced on *nitric acid*. The new prices are given as 5¼@6¼c. per lb. for the 36 deg. in carboys, 6¼@7¼c. for the 38 deg., 6¾@7¾c. for the 40 deg. and 7½@8½c. for the 42 deg. Business continued along narrow lines, although the total quantity of acid changing hands is said to be good.

COAL-TAR PRODUCTS

The reports of different quarters of the coal-tar products market during the past week have been very much mixed. Some sellers have found an improvement, while others say they can find no change in the dullness that has been steadily manifest for weeks. The increased number of textile plants which have been put into operation during the past month or so will unquestionably result in a growing demand for colors, but so far this increased demand has failed to reach intermediate manufacturers. In no section of the market have second hands figured so largely as in this and before a real improvement can come in business it will be necessary to reduce the number of profits on a single transaction to a minimum. Basic conditions in this market are decidedly in favor of the American manufacturers in being protected, at least for the time being, from any form of foreign competition which has been such a factor in the chemical market. The actual volume of business during the past month has been better than the attitude sellers seem to indicate, since they are chiefly concerned over the fact that prices have been sacrificed in a great number of cases. Prices in general continued soft, with resale lots of many commodities in more or less distress. The crude products seem to be moving in large volume but still confined to quantities covering short periods. Prices in this branch of the market are showing more steady than the intermediate market and now that better demand is in prospect the present quotations have an air of firmness.

Prices on *benzene* continued practically unchanged. The demand has been somewhat more active, but is still below normal, especially for carlot business. Quotations are given as 30@35c. per gal. for the pure grade and 28@34c. for the 90 per cent in tank cars and drums. The inactivity in the dye trade, which has prevented any considerable amount of business recently, is passing and increased activity among dye makers will bring about a revival of interest in this commodity, as stocks in consumers' hands are conspicuously low. The *naphthalene* market in second hands is reported considerably strong. The flakes can still be found in some quarters as low as 8c. per lb., but the majority of holders of spot goods are setting their selling price at 8½c.

per lb. Producers are quoting 9@10c. on flakes and 10@11c. on balls, all f.o.b. works.

Some inquiry for *aniline oil* has been noted during the week, but prices are still very unsteady and are quoted over a wide range by holders of stocks. Resale stocks are available at 22c. per lb., drums extra. Producers are quoting all the way up to 28c. per lb. The increased volume of business being done by the textile industry is expected to reflect itself in the market in the very near future. The market on *beta-naphthol* has been of a very limited nature during the week, but has shown some improvement over other weeks. Holders are quite firm on price and have turned down bids of 32@33c. per lb. for spot material. The general quotation for resale material is 34c. per lb., with producers' figure ranging from 40@45c. per lb.

Resale lots of *para-nitraniline* are offered as low as 85c. per lb. Producers are quoting \$1.05@\$1.15 per lb., according to quantity, but are willing to shade these figures on firm business. Factors report a limited routine demand for *ortho-toluidine*. The available supply is of sufficient volume to meet present requirements and sellers are steady in their views on prices, ranging from 25@30c. per lb. Trading in the market on *para toluidine* continues along quiet lines with the movement chiefly confined to small quantities into consuming channels. Prices are fairly steady at \$1.40@\$1.50 per lb., depending on quantity. Prices on *H acid* are still heard over a rather wide range. Producers are holding for as high a figure as \$1.60 per lb. for limited amounts and name \$1.50 for round lots. Outside holders are quoting all the way down to \$1.10 per lb. for a fair quality. Other quotations generally heard ranged from \$1.25@\$1.35 per lb.

VEGETABLE OILS

Importers of *China wood oil* report quiet trading, with prices in some quarters unsettled. It was reported that scattered lots could be picked up at 9½c. per lb. in barrels, while for carlots for nearby delivery 9c. could be done on a firm bid. The Coast market was nominal at 8c. per lb. Reports on the conditions on *coconut oil* covering round lots were rather conflicting. In some quarters it was said that the situation was somewhat firmer, while advices from the Middle West indicate that offerings were made at concessions. Ceylon grade in barrels closed at 9¼c. per lb., while Cochin closed at 10½c. per lb.

The market for *linseed oil* was dull and the undertone, taken as a whole, was barely steady. A few inquiries came to light, but these were more or less in the nature of sounding sellers. So far as nearby oil is concerned, it was possible to draw offerings from crushers on a basis of 67c. per gal. in carlots, while in a few cases firm bids could have bought merchandise at some concession. Spot oil in lots of 5 and 10 bbl. was available at 70@71c. per gal. The market for *palm oil* was reported quiet and unchanged at 7¼c. per lb., immediate or prompt shipment. *Niger oil* held at 6½c. per lb. The steady position of the exchange tends to hold values on this commodity. There were offerings of domestic crude *peanut oil* for immediate shipment from mill at 6c. per lb., indicating that the market was somewhat irregular. The demand in general was reported dull.

The Iron and Steel Market

PITTSBURGH, March 4, 1921.

On the whole there is perhaps a slight downward trend in finished steel according to minimum prices quoted by independents, but the outstanding feature of the market situation is the fact that prices are declining so little when all or nearly all of the independents are willing to make further cuts in prices for the sake of getting an actual tonnage of orders. The difficulty is that consumers are unwilling to buy at any price. Repeatedly mills have solicited buyers to make bids, only to be met with the response that no steel is required just now.

The Pittsburgh Steel Co. has begun to quote wire nails at \$3 base, or 25c. a keg under the Steel Corporation price. Several weeks ago the Midvale Steel & Ordnance Co., which is generally credited with having instituted the price-cutting movement, began to quote nails at \$3.10, but subsequently the price was withdrawn, at least as an open quotation. The

Pittsburgh Steel Co., however, explains that it quotes \$3 openly because at least two other producers have been quietly doing \$3 of late.

Plates are still quotable at 2.10c. on ordinary business, bars at 2c. and shapes at 2.10c., though in each case it is understood that on a sufficiently attractive order \$1 or \$2 a ton less could be done, the difficulty being that attractive orders are not being offered in the market. An interesting point is that the Steel Corporation has just sold 3,000 tons of plates to a regular customer at its price of 2.65c.

Black sheets are quoted at 4.10c. by more producers than formerly, with intimations that 4c. could be done on a sufficiently attractive order. Galvanized sheets are generally quotable at 5.25c., with likewise a little leeway.

Report has it that standard railroad spikes could be bought at 3.35c., against 3.65c., the regularly quoted price, hot-rolled strips at 3.05c. or less, against 3.30c., and cold-rolled strips at 6c., against 6.25c. Cold-finished steel bars can be purchased even in less than carload lots at 3.35c., against a nominal or official quotation of 3.60c.

STEEL CORPORATION POSITION

The United States Steel Corporation evinces no intention or reducing either its prices or its wage rates immediately. Some of the corporation's customers have expressed themselves as opposed to price reductions at this time and there is no evidence that buyers in general are waiting for lower prices or would be induced to buy more freely even if prices were greatly reduced. As to wages, which obviously could not be reduced when shipments are being made at old prices, the cost of living has not declined sufficiently to permit of a fair and permanent readjustment being made. With light operation and a distribution of employment the earnings of the men are reduced while the cost of living has not greatly declined.

PRODUCTION

Operations at some of the independent mills have increased, but on the whole there is no increase, and common estimates are that the independents generally are not operating at over 20 or 25 per cent of capacity, which may be estimated at 30,000,000 gross tons of ingots per annum. The Steel Corporation has been operating this week at between 60 and 65 per cent of capacity, which is approximately 22,500,000 tons. Production therefore may be taken at 7,000,000 tons a year by the independents and 14,000,000 tons by the Steel Corporation, or 21,000,000 tons altogether, which is just 40 per cent of actual capacity as nearly as can be estimated. This rate is undoubtedly in excess of the actual rate at which steel is now being consumed, and however business may be distributed among the mills in the future, the total production is likely to decline for several weeks before there is any tendency toward an upturn.

Production of pig iron is at the rate of 22,000,000 or 23,000,000 tons a year, or 50 per cent of estimated capacity, not theoretical capacity. The merchant furnaces as a whole are producing at not over about one-third of capacity. A considerable part of the output is being stocked, and there are prospects of several merchant furnaces blowing out within the next few weeks. The steel interests do not seem to have reduced their pig iron production in all cases as much as their steel production, and some of them have accumulated tonnages of pig iron that look large in present conditions.

Foundry pig iron has declined 50c. in the valley market, with sales at \$26.50 valley. Bessemer remains quotable nominally at \$27 valley, with no interest manifested. The last open quotation on basic iron was \$25 valley, and merchant furnaces would willingly sell at this price, hoping to reduce costs while operating sufficiently to avoid loss. At best, of course, the \$25 price would represent taking a loss on ore bought at last season's prices, it being understood that the 1921 prices will be down, perhaps by as much as \$1. Some steel works iron could probably be bought at well below \$25, but bids are not being made. It seems to be established that one odd lot of basic of 600 or 700 tons has just been sold at \$23 to close out. From all this it can be seen that the pig iron market has not reached a stable level by any means.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

MONTGOMERY—The Jenkins Brick Co. has plans under way for extensions and improvements in its plant. The present kiln capacity will be increased, and corresponding enlargements made in other departments. New machinery will be installed, including pulverizing and other equipment.

Arkansas

HOPE—The Arkansas-Texas Oil Co. is considering plans for the construction of a new oil refinery on a local site. A pipe line extending to the oilfields will be installed. W. T. Knight is president.

California

RICHMOND—The Natural Soap Co., with headquarters at San Marcial, N. M., is negotiating with the local Chamber of Commerce for a site for the erection of a new plant. It is said that the proposed factory will cost in excess of \$50,000.

EL SEGUNDO—The General Chemical Co., Los Angeles, is planning for the early operation of its new acid-manufacturing plant here, now in course of erection. The plant consists of four units, and each will be placed in service as soon as completed.

Connecticut

BETHEL—The D. J. Lane Leather Co. is completing plans for the rebuilding of its local plant, recently destroyed by fire. One large plant unit will be constructed on the same site as previously used for a number of smaller buildings. As soon as the new factory is completed, the company will remove its present branch works at Danbury to the Bethel location.

WATERBURY—The Scovill Mfg. Co., Bridge St., manufacturer of brass and other metal goods, will soon commence the erection of a new 1-story brass mill, 155 x 160 ft., brick and steel, estimated to cost about \$100,000 with equipment. Hugh L. Thompson, 57 North Main St., is engineer.

Delaware

WILMINGTON—The Wilmington Leather Co. is adjusting matters regarding insurance on the recent fire at its plant at Second and Greenhill Sts., and has preliminary plans under way for the rebuilding of the works, replacing a fire damage estimated at \$1,000,000 with machinery. The reports that the plant would not be rebuilt have been denied. James J. O'Neill is president.

Georgia

HAZLEHURST—The Carter Cotton Oil Co. is planning for the rebuilding of its plant, destroyed by fire Feb. 19, with loss estimated at \$100,000, including equipment.

Illinois

CHICAGO—The American Insulated Wire & Cable Co. will locate a copper wire rod mill here. It has purchased property at the northwest corner of Twenty-second and Fisk Sts., which is at present occupied by a 1-story plant. This plant will be remodeled at a cost of about \$100,000. Additional equipment to be installed will cost about \$200,000.

CHICAGO—The American Cereal Products Co. of Chicago has acquired the plant of the Acme Malting Co., at the northwest corner of Bloomingdale Rd. and Kedvale Ave. Alterations in this plant and purchase of new equipment is contemplated.

CHICAGO—The Goodman Mfg. Co. producer of mining machinery and supplies, electric locomotives, etc., has acquired new property at the northwest corner of Halstead and Forty-Eighth Sts., anticipating enlarged facilities due to future growth of business.

LYONS—The University Oil Products Co., 208 South La Salle St., Chicago, has commenced the erection of its proposed new local oil plant. The refining works will

consist of five 1- and 3-story plant units, totaling 50 x 1,000 ft. in size. Holabird & Roche, 104 South Michigan Ave., Chicago, are architects. H. J. Halls is president.

CHICAGO—The Mid-West Box Co. of Delaware has been organized with a capital of \$7,500,000 to take over the plants and business of the Mid-West Box Co. of Indiana, 111 West Washington St., Chicago; Mid-West Box Co. of Ohio; the Mid-West Box Co. of West Virginia, and the American Straw Board Co., Akron, O. The first noted companies specialize in the manufacture of corrugated fiber shipping cases, containers and other products, and the acquisition of the American Straw Board interests is to secure a definite supply of raw materials. Expansion plans are under way at a number of the plants of the combined company, and increased output will be arranged.

Kentucky

BOWLING GREEN—The American Producing & Refining Co. has plans under way for the erection of a new oil-refining plant, with initial capacity of about 1,000 bbl. per day. It is estimated to cost close to \$200,000 with machinery.

Louisiana

MONROE—The American Carbon Co., recently organized with a capital of \$1,500,000 by interests connected with the Southern Carbon Co., has plans under way for the erection of a new local plant for the manufacture of carbon from lignite under a special process. The new carbon, it is said, will be used primarily in refining sugar, replacing the bone black now employed. The plant with machinery is estimated to cost in excess of \$750,000.

Maryland

BALTIMORE—The United States Industrial Chemical Co., Curtis Bay, has filed plans for the erection of a 1-story plant addition, 60 x 180 ft., to cost about \$14,000.

BALTIMORE—Frank G. Kitchen has leased a building at Hollins St. and Calverton Rd., adjoining the factory of the Lipps Candy Co. and previously used in connection with this business, for the establishment of a new plant for the manufacture of varnishes, stains, oils and kindred specialties. Equipment for this purpose will be installed at once.

CANTON—The Standard Oil Co. has acquired a large tract of land adjoining its local plant, heretofore held by the Canton Co., and will use the property for proposed future additions. No announcement has been made as to time of erection. The company has also taken title to a number of pieces of property on First St., Baltimore, for use in connection with its new terminal at this location.

CUMBERLAND—The American Cellulose & Chemical Co. is planning for operations at its new local plant early in the summer. The different structures are now nearing completion, forming the initial units, and machinery will be installed promptly. This section of the plant is said to represent an investment of \$4,000,000. The entire project as planned, covering additional manufacturing units, will cost in excess of \$8,000,000.

Massachusetts

FRAMINGHAM—The Dennison Mfg. Co., manufacturer of paper specialties, has plans under way for a new 4-story addition, 70 x 100 ft. Monks & Johnson, 99 Chauncey St., Boston, are architects.

Minnesota

MINNEAPOLIS—The Hannepin Atomized Fuel Co., 500 Security Bldg., is having plans prepared for the construction of a new 1-story fuel-crushing plant at St. Paul. The works will cost about \$150,000 with machinery. C. L. Pillsbury, 1206 Second Ave., is engineer.

Missouri

KANSAS CITY—The Corn Products Refining Co., 17 Battery Pl., New York, has construction well under way on its new plant at North Kansas City, and will place the work in service at an early date. Mis-

cellaneous contracts for completion work have been let. The plant will consist of three complete units, and represents an investment of about \$7,000,000.

New Jersey

NEWARK—G. N. Bick has filed plans for the erection of a new plant at 71-75 Paris St., to be 42 x 62 ft., for the manufacture of chemicals. The factory will include a laboratory.

BAYONNE—The International Nickel Co. has filed plans for the erection of a number of 1-story buildings at its plant at the foot of Twenty-second St., to cost about \$18,000.

BLOOMINGDALE—Lissberger Bros., operating the Somerville Iron Works, Somerville, N. J.; the Eagle Smelting & Refining Works, Newark, and other industries in the state, have leased the former plant of the Morris County Chemical Co., East Bloomingdale, for the establishment of a chemical, dye and affiliated products experimental plant. Operations will be inaugurated at once under the direction of Dr. S. A. Molnar, chemical engineer. The plant was at one time occupied by the Butler Chemical Co., now defunct, and later, by the New Jersey Chemical Co.

NEWARK—In addition to its proposed new plant at Beaufort, S. C., recently announced, the Ocean Leather Co., Inc., 33 New York Ave., is planning for the establishment of a similar factory for the treatment of shark skins at Hyannisport, in this same vicinity. It is said that the plant will be one of the largest of the company's works, and will be equipped for all features of fish leather production. It will be operated on an all-year basis.

New York

BUFFALO—The University of Buffalo has filed plans for the erection of a new 3-story chemistry building at Main St. and Niagara Falls Blvd. It is estimated to cost about \$400,000. A large laboratory will be installed.

Ohio

CAREY—The Hume China Co. is completing plans for the construction of a new 1-story pottery, 150 x 500 ft., and will soon call for bids. It will be of brick, tile and concrete. W. W. Matchett, 408 Alliance Bank Bldg., Alliance, O., is architect. George H. Hume is president.

SANDUSKY—The Hinde & Dauch Paper Co., manufacturer of corrugated fiber boxes, containers, etc., is having plans prepared for the erection of its proposed new paper mill and factory at Fort Madison, Ia. The plant will be about 100 x 340 ft., and with machinery is estimated to cost close to \$1,000,000. The Ferguson Co., Columbus, O., is engineer and architect.

DOVER—The Dover Coke & By-Products Co. is arranging for the immediate construction of four additional ovens at its plant. Improvements will be made in a number of present oven units at the works.

Pennsylvania

PHILADELPHIA—The Gulf Refining Co., 21 State St., New York, and Pittsburgh, Pa., has abandoned plans temporarily for its proposed new oil refinery to be located at Girard Point, Philadelphia. The company acquired a tract of about 70 acres of land some time ago at this location and has done considerable preliminary work, including the construction of a reinforced-concrete wharf, 55 x 840 ft. The company is now operating a local plant at Fifty-eighth St. and the Schuylkill River.

South Carolina

COLUMBIA—The H-W Chemical Co., recently organized, is planning for the establishment of a local factory for the manufacture of chemicals and affiliated products. A local building has been secured and equipment will be installed at once. The company is headed by J. S. Hammack and J. W. Wilson.

CHESNEE—The Crawley Gin Co., recently organized, will operate a local cottonseed oil mill. T. A. Sawyer is president, and John B. Cash, secretary and treasurer.

Texas

SWEETWATER—The Sweetwater Refining Co. has acquired a local site and has plans under way for the construction of a new oil refinery.

LINDEN—The Pratt Bros. Iron Ore Development Co., Minneapolis, Minn., has commenced preliminary work on its proposed new ore-crushing plant at Bowieville, near Linden. The works will comprise departments for crushing, screening and roasting, with initial equipment to provide for a capacity of about 400 tons per day. At a

later date it is proposed to install a magnetic process plant for ore treatment, supplanting the roasting method. The company's holdings in this district are estimated to contain about 6,000,000 tons of ore.

BURKBURNETT—The C. F. Noble Oil & Gas Co. is planning for the rebuilding of the portion of its local gasoline plant, recently destroyed by fire with loss reported at about \$18,000.

Washington

CENTRALIA—The Steel Casting Co. has been incorporated by officials of the Ten-nent Steel Casting Co., Tacoma, Wash., with a capital of \$75,000, to operate a local plant. Plans are being perfected for the new works, to be equipped for the production of high-grade steel castings.

New Companies

THE KEMIKO Co., Newark, N. J., has been incorporated with a capital of \$50,000 to manufacture chemicals. The incorporators are Adelbert L. Vandenburg, Harold W. Yapp, and Henry Faust, 112 South Seventh Street.

LOMBARD & Co., INC., Boston, Mass., has been incorporated with a capital of \$350,000 to manufacture grinding wheels, abrasive materials and kindred products. The incorporators are John H. McGill, Walter L. and William H. McGill, 21 Oxford Street, Winchester, Mass.

THE SPECIAL PRODUCTS Co., Hopewell, Va., has been incorporated with a capital of \$250,000 to manufacture paints, varnishes and affiliated products. The incorporators are J. C. Fleming and Clay Littleton.

THE WICOMICO FARMERS' ASSOCIATION, Salisbury, Md., has been incorporated with a capital of \$50,000 to establish and operate a fertilizer manufacturing plant under co-operative plans. The incorporators are William C. Mitchell, E. Dale Atkins, and William M. Cooper, Salisbury.

YARDLEY & Co., LTD., New York, has been incorporated with a capital of \$100,000 to manufacture soap and affiliated products. The incorporators are C. Smith, R. E. Gardner and L. M. Townsend, 48 Wall Street.

THE ROFF COTTON OIL Co., Ada, Okla., has been incorporated with a capital of \$50,000 to manufacture cotton oil products. The incorporators are P. A. Norris and C. L. Griffith, Ada; and W. R. Brents, Sherman, Tex.

THE MIDDLETON & PETERSON Co., Savannah, Ga., has been incorporated with a capital of \$30,000 to manufacture cotton oil products and kindred specialties. The incorporators are M. L. Middleton, and W. M. Peterson.

THE AMERICAN CARBON Co., Monroe, La., has been incorporated with a capital of \$1,500,000 to manufacture carbon products. The incorporators are M. C. Redmond, and Earl P. Hartshorne, Monroe.

THE UNION STONEWARE Co., 400 West Kinzie St., Chicago, Ill., has been incorporated with a capital of \$50,000 to manufacture glass, pottery, porcelain and other ceramic products. The incorporators are W. P. White, E. S. Hoyt and W. H. Putnam.

THE LIMESTONE PRODUCTS Co., Black Rock, Ark., has been incorporated with a capital of \$400,000 to manufacture hydrated lime and other lime products. The incorporators are William H. Woodruff, Jonesboro, Ark.; C. E. Scott and D. S. Alessi, Springfield, Mo.

THE SPANISH MOSAIC TILE Co., Washington, D. C., has been incorporated under Delaware laws with a capital of \$25,000 to manufacture floor and wall tile, mosaics, etc. The incorporators are M. A. Cahill, Redick W. Ridgely and William A. McGuire, Washington.

THE AMERICAN FIBER CONDUIT CORP., Fulton, N. Y., has been incorporated with a capital of \$350,000 to manufacture fiber conduits and other fiber products. The incorporators are G. M. Fanning, G. Crossman and R. F. Freeman, Fulton.

DOE & INGALLS, INC., Boston, Mass., has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are Robert C. Ingalls, Charles E. Haywood and Willis H. Doe, 236 Milk St.

THE VEREX CHEMICAL Co., Lakewood, N. J., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemical products. The incorporators are Lester H. Sparks, Arthur R. Smock and William J. Norton, Lakewood.

THE M. & M. MFG. Co., Tipton, Ind., has been incorporated with a capital of \$10,000 to manufacture chemicals and chemical byproducts. The incorporators are E. L. and T. M. Mitchell, and J. W. Meader, Tipton.

THE DUNBAR OIL Co., 43 East Ohio St., Chicago, Ill., has been incorporated with a capital of \$100,000 to manufacture refined oil products. The incorporators are J. O. Karstrom, E. W. Spicer and R. B. Kee.

THE KARVA LABORATORIES, INC., New York, has been incorporated with a capital of \$15,000 to manufacture chemicals and affiliated products. The incorporators are J. Schron, L. L. Leventritt and R. S. Mazzola, 128 Broadway.

THE PENNSYLVANIA METAL REDUCTION Co., Pittsburgh, Pa., has been incorporated with a capital of \$10,000 to operate a metal-refining plant. E. F. Straw, Pittsburgh, is treasurer.

THE ALLIED RUBBER COMPANIES, INC., Calvert Bldg., Baltimore, Md., has been incorporated with a capital of 500,000 shares of stock, no par value, to manufacture rubber products, gutta percha specialties, etc. The incorporators are William Leary, James A. Curtis and Leslie E. Mihm.

THE PARKER RUBBER MFG. Co., Boston, Mass., has been incorporated with a capital of \$125,000 to manufacture rubber goods. The incorporators are David H. Finberg, Philip Finberg, and Harry D. Finberg, 621 Albany St.

KEINER & Co., Newark, N. J., have been incorporated with a capital of \$125,000 to manufacture chemical products. The incorporators are Erich G. Keiner, Wilmington, Mass.; Irving Willner and Jacob Lubetkin, Newark.

THE DUQUESNE SHEET GLASS Co., Pittsburgh, Pa., has been incorporated under Delaware laws with capital of \$100,000 to manufacture sheet glass specialties. The incorporators are Thomas H. Chadwick, Pittsburgh; George W. Fees, Arnold, Pa.; and John A. Wilson, Wilkinsburg, Pa.

THE IMPERIAL JAPANING & ENAMELING WORKS, INC., 408 West Grand Ave., Chicago, Ill., has been incorporated with a capital of \$100,000 to manufacture enamelled products, japanned goods, etc. The incorporators are John A. Skailand, Joseph V. Janda and William Link.

THE RICHFIELD GRANT OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$1,500,000 to manufacture petroleum products. The incorporators are W. J. Honam, Los Angeles; J. E. Michel, Corcoran, Cal.; A. W. Miller, Riverside, Cal.

THE TAYLOR RUBBER Co., Detroit, Mich., has been incorporated with a capital of \$1,000,000 to manufacture rubber products. The incorporators are Hugh Thorburn, 510 Newport Ave., Detroit; and Parker G. Ballon, Rathbone, Ont.

THE MCLAIN OIL CORP., New York, has been incorporated with a capital of \$175,000 to manufacture refined oil products. The incorporators are J. D. Martensen, C. W. Osborne and J. F. Renfro, 212 West 68th St.

THE EXCHANGE CHEMICAL Co., Bangor, Me., has been incorporated with a capital of \$50,000 to manufacture chemicals and byproducts. The incorporators are Julius Byer, Moses L. Friedman and Max S. Kominsky, Bangor.

THE AMERICAN APPARATUS GLASS Co., Vineland, N. J., has been organized to manufacture scientific laboratory glassware. The company is headed by S. A. Giederoye, president; W. Shewell Hood, vice-president and general manager; and Otto Lind, treasurer and superintendent.

THE KENTUCKY SHALE PRODUCTS Co., Bardstown, Ky., has been organized to manufacture brick and other burned clay products. The company is headed by J. B. Beam, L. B. Samuel and J. A. Fulton, Bardstown.

THE NEW PROCESS METAL CORP., Newark, N. J., has been incorporated with a capital of \$250,000 to manufacture refined metals and metal alloys. The incorporators are Walter F. Young, Newark; Sydney T. Edge, West Paterson; and Frank J. Morris, West Orange, N. J.

THE CHRISTENSEN & OLSEN FOUNDRY Co., 1713 Carroll Ave., Chicago, Ill., has been incorporated with a capital of \$5,000 to manufacture aluminum, brass and bronze, castings, etc. The incorporators are Arthur O. Olsen and S. L. Christensen.

THE SUPERIOR PRODUCTS Co., Cortland, N. Y., has been incorporated with a capital of \$15,000 to manufacture paint and kindred products. The incorporators are A. A. Loomis, C. M. Smith and C. R. Hall, Cortland.

Capital Increases, Etc.

THE TEXAS Co., 17 Battery Pl., New York, operating oil refineries at various points in Texas, has arranged for an increase in capital from \$130,000,000 to \$143,000,000.

THE MICHIGAN PAPER Co., Plainwell, Mich., has increased its capital from \$1,000,000 to \$3,000,000 for expansion.

THE NOXON CHEMICAL PRODUCTS Co., 22 Hackett St., Newark, N. J., has filed notice of increase in capital from \$150,000 to \$325,000 for general operations, expansion, etc.

THE CHEMICALS INDUSTRIALS CORP., New York, has filed notice of increase in capital from \$29,000,000 to \$33,000,000 for proposed extensions.

THE SIMPSON CLARK GLASS Co., 164 West Randolph St., Chicago, Ill., has filed notice of increase in capital from \$75,000 to \$100,000.

THE GEORGE STRATFORD OAKUM Co., Cornelison Ave., Jersey City, N. J., manufacturer of marine oakum, etc., has filed notice of increase in capital from \$60,000 to \$500,000 for proposed expansion.

THE CHEMICAL RESEARCH Co. OF AMERICA, Boston, Mass., has filed notice of change of name to Korite Products, Inc., to manufacture chemical specialties.

THE GILMAN PAINT & VARNISH Co., Chattanooga, Tenn., manufacturer of paints, oils, varnishes, etc., has increased its capital to \$75,000. W. D. Gilman is president.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon April 26 at Rochester, N. Y., for luncheon.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

REFRATORIES MANUFACTURING ASSOCIATION will hold a meeting at the Hotel Pennsylvania, New York City, March 17 to 19.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: March 11, American Chemical Society; March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Legislation That Passed

And Legislation That Failed

THE chemical industries cannot find a great deal of comfort in the legislative status at the close of the last session of Congress, for many of the measures in which these industries are interested failed of passage. Moreover, it should be understood that the new Congress which will convene shortly will start afresh in all these matters, just as though there had not been any legislative effort made by the previous Congress. Each bill, no matter how far it had advanced in the last session, must be introduced, referred to committee, reported to each house, acted upon, sent to conference to adjust differences between the two houses, and the conference report acted upon in each house, and transmitted to the President for signature. It is easily seen why it is such a shame to have legislation fail at the end of a Congress when all this effort and expense must again be incurred for the passage of bills which were previously so near enactment.

Conspicuous among the incomplete legislation at the end of the Congress were the Army and Navy appropriation bills. In these two supply measures are included the money for chemical warfare, for the helium investigations and for other military and naval activities. The separate bill providing for the Fixed Nitrogen Corporation also failed of passage, although it was approved by the Senate in much emasculated form following amendments proposed by Senators WADSWORTH and LENROOT. This bill, which would have provided for the continued operation of the Muscle Shoals nitrate plant, died because the House Committee on Military Affairs under the chairmanship of Representative KAHN held the bill without action from Jan. 14 to the end of the session of Congress. However, it is doubtful whether the bill would have passed in any useful form even if it had been reported by this committee, since the appropriation for the Muscle Shoals project for power development through the Wilson dam was defeated. The defeat of this power measure was doubtless the result of the co-operation of two groups, one of which sought economy in expenditures, the other of which opposed the bill on the ground of policy, objecting to the Government entry into further power development, especially under circumstances where the power project was so closely associated with the nitrate plant.

In connection with power matters, special notice should be given to the failure of Congress to provide adequately for the Federal Power Commission. This and the failure to provide for reorganization of the Patent Office will mean that these two important engineering services of the Government will either mark time or actually slip backward during the coming fiscal

year unless some new legislation is successfully handled in the coming session of Congress. Without a Patent Office adequately manned, business is sure to suffer. Without a Power Commission provided with suitable personnel all industry will be condemned to delay in its effort to secure adequate water power. No measure of economy can possibly justify these items of saving in appropriation. It is simply an unfortunate result of our political system that permits two Senators (SMOOT and JONES) to defeat the Power Commission measure and one Senator (NORRIS) to hold up the Patent Office bill.

It is not surprising to record that the duty-free importation of glassware and chemicals and the dyestuff import legislation remained without favorable action in the Senate. Both these measures and the emergency tariff legislation, which was vetoed by the President, will doubtless be reconsidered in connection with the general tariff revision which will be a leading measure in the new Congress. It is to be hoped that these technical matters will thus receive most sympathetic consideration in the Fordney tariff law, which will undoubtedly be enacted at an early date unless it is decided as a matter of policy to reenact the Payne-Aldrich tariff as an immediate but temporary measure. It is rumored that this may be done in order that the Republican policies of protection for industry provided by the Payne-Aldrich law may at once supersede the Democratic free-trade idea which was, of course, basic in the Underwood law of 1913, which still stands on the statute books.

With such important matters as the two remaining appropriation bills, the whole problem of taxation, tariff and revenue legislation, and the responsibility for some sort of peace treaty upon the hands of the new Congress, much minor legislation will doubtless suffer. However, it is likely that the Congressional commission appointed to investigate the needs and possibilities of Government reorganization and creation of the new Department of Public Works will be busy during the coming year. This commission under the chairmanship of Senator SMOOT is already engaged upon certain work which will doubtless lead to bills to supersede those introduced in the last Congress which received no attention after the appointment of this commission was agreed to. Incidentally this reorganization of the Government departments, in which Secretary of Commerce HOOVER will doubtless have a large influence, has an important bearing upon budget legislation. In view of this fact the technical branches of the Government service, which are those most vitally concerned, may receive the attention which they deserve, being carried forward to prominent place in the legislative program because of the desire to have the budget measures adequately considered at an early date.

What We Want Is Orders

VERY fortunately one fashion is going out—that of counting up the “needs” in steel of the railroads, or the United States as a whole, or the world. Everyone can recall how much talk there has been along this line and everyone can see that we have got nowhere with it. What we want is orders.

Needs are of no importance unless they can be expressed, and then they do not count unless they can be met. There must be the ability to buy and the ability to produce. We certainly have the ability to produce, although we did not have it during the first nine months of last year. Then there was heavy demand, yet the steel mills did not average over an 80 per cent operation.

In a measure the transaction of business is a cycle of operations. One buys from another, he from a third and so on around to the first again. One line cannot be very active unless other lines are active. The farmer raises corn, the breakfast food factory buys it, the story writer consumes the corn flakes and the farmer subscribes for the magazine. A partial exception to the ordinary circle of transactions occurs when there is construction work, for it is set not against present consumption but prospective consumption. If the respective prices of corn, corn flakes, stories and magazines have proper relationship, no matter what the basis, business can be transacted, but construction work must cost in relation to values in future. Hence when prices in general are declining, construction work lags, while when prospects are for higher prices investors hasten to take hold.

As steel is used largely for construction purposes, its selling price needs to be in relation to future values in general. In addition to this there is the situation that there are large “needs” for steel, yet the needs are not expressed in orders, because those who need steel cannot afford to buy. The gap can be bridged by movement from each side, by increasing ability to buy and by the quantity of steel available for a given sum of money being increased. The per ton price of steel can never mount so high as to prevent steel from being used for watch springs, but it can be too high to warrant the building of a given bridge. The steel-making capacity is so large that it requires demand from all possible sources. Steel must make as wide a market for itself as can be found.

We have had enough of this talk about there being great needs in steel, of the world being short of steel. Let the talk be dismissed by a sweeping admission that it is all true. The vital fact today is that the great need is for steel orders. The constructive work to be done is in getting down the cost of producing steel. There has been some talk lately in various quarters about the necessity of steel prices being reduced. The matter of selling price is of very little moment just now. The steel price list is ephemeral. There is no demand in the market just now, and if there is an improper gap between production cost and market asking prices the gap will no doubt be reduced in ample time. The vital thing is the cost of production, which is too high. The labor cost is too high. Wage rates are too high in relation to the cost of living and the cost of living is too high. Wholesale prices are down and the retail storekeeper is either making too much money or is not performing his function of distribution properly. Freight rates are altogether too high. The amount of money that must be

paid so that a ton of finished steel may be delivered to the consumer is altogether out of a natural proportion, chiefly because the railroad payrolls, on which freight rates are based, have been entirely too high and out of all proportion to the service performed by the railroads. Analyses that may be made of “what becomes of the railroad dollar” vary widely because conditions change so rapidly. The railroad operating ratio, operating expenses to operating revenues, was 70.57 per cent in 1917 and 93.53 per cent in 1920, while now it is a still different thing. One illustrative comparison can be made, however, that the railroad payroll has lately been running at about \$3,700,000,000 a year while the extra half per cent the Interstate Commerce Commission accorded the railroads under the permission given by the transportation act would, if the railroads were able to collect it by having enough traffic, amount to about \$95,000,000. There is a ratio of about 39 to 1, certainly very suggestive. The steel industry has already addressed itself to these two big items, of its wages and its freight bills, as well as to many other smaller items, for the purpose of reducing costs and making a market for steel.

Labels to Inform And to Deceive

“MADE in Germany,” “Made in Nippon” and “Made in U. S. A.” are all labels of distinct industrial significance. It is well, therefore, that the Federal Trade Commission is giving particular attention just now to the deceptive practice which is creeping into American commerce whereby certain foreign interests and American importers seem to be co-operating in an effort toward deception of the American public and the defeat of legitimate American industry.

The Federal Trade Commission has just announced (March 5) a citation of a New York manufacturing company to show cause why it should not cease mislabeling the device which it sells. On the outside of this device a brand “White House” appears, and the company even labels the exterior portion of the device “Made in U. S. A.” to convey the impression that the entire device is of domestic production. As a matter of fact the main portion of this device is made in Germany, and careful examination of the interior of the instrument shows this fact. Obviously the trade practice is a vicious one and it is to be hoped that the commission will be successful in eliminating this type of bad practice.

It is very unfortunate that each unit of chemical production, such as dyestuffs, intermediates, pharmaceuticals, etc., cannot be clearly labeled as to its original source. It might even be worth while for the American chemical industry to appeal to Congress for legislation requiring that materials important to domestic industry should be labeled as to their source. Such a plan would be entirely feasible, for on repackaging it would not be at all difficult to label properly and conspicuously the container with the source of original production. The only question would be to decide when a material refined or purified in this country has ceased to be essentially of foreign production and become properly “naturalized” as an American product. Yet there is no question that instruments and other articles of manufacture which can easily be labeled should be properly so stamped.

Actual Smoke Damage

Must Cause Visible Markings

IT MUST be a source of deep satisfaction to Dr. O'GARA and his assistants to find that the conclusions they reached so early in their researches on the smoke problem have received the unqualified assent of independent investigators. The main results of their studies, started about seven years ago, are now fairly widely known and accepted by plant pathologists. Officials of their own concern, the American Smelting & Refining Co., have also been convinced of the soundness of the deductions, as witness the expenditure of several hundred thousand dollars for new flue and stack systems at various plants. While a marked reduction in the number of complaints from neighboring farmers immediately followed the completion of such improvements, the final test of all remained—whether a smelter operating under correct conditions, as determined by the researches, would be permitted to continue so to operate by a judge when deciding a so-called "smoke suit"; that is to say, whether a court could be thoroughly convinced of the efficacy of modern methods of eliminating damage by sulphur smoke.

That this final test has been successfully passed is apparent from a perusal of the report rendered by Prof. ROBERT E. SWAIN, acting as commissioner, to Federal Judge JOHNSON. Judge JOHNSON expressed the opinion over a year ago that the A. S. & R. Co. officials had "practically solved the smoke problem." They were then given the opportunity of suggesting operating stipulations embodied in an interlocutory decree, which must have been done by them with a knowledge that they could operate with a good factor of safety. Dr. SWAIN'S most painstaking and independent researches now give that company a clean bill of health.

How far apart the parties to a litigation may be is apparent from the fact that only a few years ago most operating companies stoutly contended that only solid matter in smelter smoke was dangerous, and since gases could easily be cleared from fume they were doing no damage. Farmers, on the other hand, were not able to recognize the true enemy, but were sure that in some cases a low yield of second grade crops resulted even when visual plant damage was entirely absent. Recognition that sulphur dioxide is the great trouble maker is no less an achievement than that plant damage to be real must be visible. What a task is the latter can be appreciated by any one who has tried to replace prejudice or fear by reason.

Dr. SWAIN bases his findings on the fact that repeated fumigation of plants with concentrations of sulphur dioxide too slight to give rise to foliar markings will not cause injury by reducing their vitality or the crop yield, even though visible typical discolorations are not produced. In other words, he assumes that the theory of "invisible injury," the "unsichtbare Beschädigungen," advanced especially by some of the earlier German investigators is untenable. That theory has never been supported by any conclusive evidence.

A turning point in the investigation of the effects of smelter smoke on plant life occurred early in the work of the Selby Smelter Commission when MARSTON and WELLS devised a method for the determination of sulphur dioxide which will yield results of a high degree of accuracy even at very low concentration. With this method at hand the way was at once open to a much more accurate control of fumigation experiments.

It was soon demonstrated that sulphur dioxide is absorbed very rapidly by soil, and by vegetation with which it is in contact. Sulphur dioxide in the air of a closed fumigation cabinet containing plants was also found to decrease rapidly. This observation revealed only one more weakness to add to those already recognized in the older methods of fumigation, and it was not long until apparatus was developed for the fumigation of plants by moving currents of air, rather than by still atmospheres, a type of apparatus used in all important recent work.

Therefore we now have every reason for believing that sulphur dioxide is freely tolerated at concentrations which are below those which will produce foliar markings and hence visible injury. In all probability SO_2 is even directly utilized by plants and there are no effects, immediate or remote, on their general metabolism which lead to a lowered vitality, to any interference with the processes of growth or reproduction, or to any reduction in crop yield. When the limiting concentrations under the prevailing conditions of humidity, light, temperature and duration of exposure are exceeded, resulting in injury, this is primarily a local injury, and quickly leads to discolorations which are quite typical and pronounced. When this point is reached, and not until then, can it be claimed that injury has been done.

A Review on Book Reviewers

THE Valentine Number of *Life* makes a few comments that should not be overlooked by all who write or read book reviews. "T. L. M." states that he is quite positive that book reviewers as a class are wholly misunderstood. Their nice sense of honor prevents them from associating with authors whose books they review, their relationships being with people of a lower order, such as publishers and editors. Their only knowledge of authors is of necessity derived from the past, and when one reads that ARISTOPHANES was extremely vulgar, that GOETHE was undomestic in his habits, that SHAKESPEARE deserted his wife, that SAMUEL JOHNSON gorged himself and that SHELLEY was excessively irreligious, it is quite natural that book reviewers should view all authors with distrust. The simple fact that any author writes a book is indeed quite likely to prejudice the book reviewer against him.

The complaint is that they do not actually read the book they review but use it as a peg to hang a few pet thoughts on, and not to tell what it is or what it ought to be. The fact is, of course, that reading the books is not necessary. It is not the province of book reviewers to tell what is in a book. If they did this there would be no use in offering the book to the public as food for the mind. It is only necessary to give their opinion after analyzing samples taken here and there after the fashion of a chemist working on coal. They should also have themselves under such control as to restrain themselves from writing anything clever about the book, merely for the sake of being clever, without regard to the damage done to the author and publisher.

All the big bow-wow book reviewers who are obliged by necessity to read one or even two books a day in order to keep up with the literary profession should certainly be provided with helpers, who might be apprenticed to their masters for a term of years before being classed as reviewers.

Readers' Views and Comments

Compensation of Chemists and Salesmen

To the Editor of Chemical & Metallurgical Engineering

SIR:—At a time when our various chemical societies are paying so much attention to the development and promotion of chemical industry, it may be well to investigate the compensation which these industrials are paying their chemical and technical employees. One thing is certain, the chemical societies themselves have up until this time done nothing of this character for their membership.

When the employers of professional chemists begin to weep and wail because of their unparalleled misfortune and the threatened destruction of their income, it is natural that one should examine some of the underlying causes of their distress. For example, we find that some of them employ college-trained chemists, and that they are paying these chemists from \$2,000 per year all the way up to \$3,000 per year. Now a capable stenographer in prosperous sales offices is frequently paid \$2,000 per year, and the "college training" which she has endured may have lasted anywhere from three to five months in some "business college" at a cost of about \$50 for tuition.

These chemists at two or three thousand per annum meet periodically in chemical societies, where they pass sundry resolutions asking for a high protective tariff for the dye industry, and are asked to vote in favor of the passage of certain industrial bills. At a recent meeting of one of these chemical societies the chairman before asking for a vote on a dye tariff bill asked the members if any one was able to state the text of the proposed bill and later asked if any one who had voted for the bill knew anything about the dye industry. The response to this question was a blank silence. And so we find that these \$3,000 per annum chemists are working in and out of office hours for the benefit of their employers. They believe that this is necessary in order to retain their positions. Here is altruism of the purest and highest sort.

Now let us see what the average employer of chemists is giving his *salesmen* in the way of compensation. He offers to a young man with a grammar school education \$2,000 a year to start as a salesman; if he possesses average ability he can earn \$5,000 per year; if he possesses special ability he is later paid \$7,500 and commissions; but if he is a star salesman he expects and receives \$10,000 to \$15,000 per year. The *star* salesman can be recognized in some firms by his acts. For example, he will send in orders to the chief chemist as to what he wants done so that the salesman's salary and commissions will be maintained. The general manager tells the chief chemist and the laboratory department of which he is the head: "You will have to get busy and help us over this trouble, for if you can't, there is no use of having a laboratory." And so the \$3,000 or \$5,000 chemist is warned to "get busy" so that a series of \$10,000 and \$15,000 salesmen may thrive.

Now let us see what the average employer of chemists is doing for his chemical adviser. He gives him a one- or two-year contract with the proviso that it may be

canceled by the employer, in case there should be any "error of judgment" on the part of the employer. He gives his chemical adviser a two-weeks' vacation, and asks him to "assign all inventions and discoveries to the company."

If on the other hand you will note how the employer finds his chemists you will see such advertisements as this: "Wanted, a young college graduate, to take charge of a new laboratory. We want a young man, one who will grow up with the business. Salary to start, \$1,500 per annum." Presently we find this same employer complaining bitterly about his "chemist," whereas in reality he has no chemist at all in his employ. All that he has is a young college graduate, and that was what he advertised for. He proudly boasts that "I pay my chemist what he is worth, and he is hardly worth the \$1,500." The employer apparently does not realize that he is actually giving this young man a post-graduate course, and the \$1,500 is merely a stipend, annuity, scholarship or bread-money while he is learning the business.

The employer will also state very seriously that many chemists are fakers, bluffers and sons of black magic. Within the last six months a representative of a prominent firm of manufacturing chemists came to me and asked if I could supply him with details for the manufacture of blue-stone or copper sulphate. He said verbatim: "I would pay as much as \$50 for this information." When told that this was somewhat out of proportion to the money which he hoped to make from the process, he stated verbatim: "Well, I think I will send my man over to the Chemists' Club to the next dinner meeting. He will be able to pick up some information there, and it will cost me only the price of a dinner." This man is the executive of a flourishing chemical company. He thrives on chemists, and he pays them anywhere from \$1,500 to \$2,500 per annum, because in his opinion "they are not worth more."

I firmly believe that the time has arrived when chemists in each state of the Union must organize state chemical societies for the purpose of:

1. Protecting college-trained chemists from unscrupulous employers.
2. Providing honest employers with chemical advisers whose record and achievements are known.
3. Providing a bureau of "professional rating" for college-trained chemists and for such other men who have scientific knowledge of a specified industry.
4. Publishing correct advice to professional chemists regarding their legal rights in matters of employment.
5. Recommending to college professors suitable courses of instruction for chemists who are to help our American chemical industries. If, however, the college professors refuse to consider recommendations, the matter should be taken up with the college executive, because he is the man who appeals to the industrial corporations for financial assistance.
6. Restricting the use of college apparatus and equipment by professors who now really carry on a practice as "consulting chemist" and who compete directly with consulting chemists who do not receive salaries as professors. From all accounts it seems that some colleges solicit funds from the public in order to maintain a private consulting practice for a college professor. In such cases it is obvious that the college is in fact maintaining a private business conducted by one of its professors. If the professor is a valuable asset to the college, he should undoubtedly receive a

salary commensurate with the salaries paid to other persons having similar experience and ability.

7. Conducting meetings at which older practitioners will discuss the "practice of chemistry as a profession." To these meetings the chemical students of colleges should be invited, so that gradually a system of ethics may be built up without the need of a printed code.

8. Supporting a journal or other publication whereby chemists throughout the state will be kept informed of the activities of chemists and chemical industries in the state.

9. Offering to banks, investors and chambers of commerce proper guidance in the choice of chemical advisors.

10. Keeping a lookout on the water supply, gas supply and garbage disposal conditions within the cities. Demanding justice and fair treatment of the citizens by the public utility companies.

11. Advising public officials when cases arise within the state relating to pollution of the air by chemical fumes or smoke, pollution of the streams by factory waste waters or sewage, special fire hazards due to dangerous location of new factories, the sale of bad milk, butter or other food products.

12. Informing the U. S. Tariff Commission and those intrusted with the framing of tariff acts if a given industry in the state is worthy of tariff protection.

13. Securing and maintaining within the state at one or more places a modern library of books on chemistry and the sciences related to chemistry. This provides for co-operation with all existing agencies of the kind by acts as well as by resolutions.

14. Maintaining friendly relations with all other State chemical societies and providing for an interchange of information.

15. Constituting special committees of competent chemists whose business it shall be to discuss and report on the preceding "purposes."

Newark, N. J.

WALTER FERGUSON.

Purity for the Pure

To the Editor of Chemical & Metallurgical Engineering

SIR:—Several of our most distinguished scientists in the teaching profession are going up and down the land expounding on a theme which might be titled "Pure Scientists Want to Remain Pure." They talk against business and commercial tendencies as applied to research and teaching with a tone almost bitter in its denunciation of business and business methods until one might be led to believe that "business" in connection with anything is a term of reproach. Now we would not quarrel with them in the matter of abstract research as long as it deals with live subjects and we would certainly favor freedom of choice in methods of procedure but must deplore the strong aversion manifested toward the ways of commerce.

Business is a science founded on economic laws quite as exact as those of chemistry, and far from being a questionable occupation is certainly as honorably practiced as other sciences, and by men of equal honor. Business men play their game for the love of the work to as great an extent as do our pedagogical friends. The main difference is that dollars are the counters in one instance and technical accomplishments in the other. Another variation lies in the fact that when the business man loses his counters he must perforce stop the play, while the college professor, supported as he is by taxation of lenient business men, can continue in the face of numerous negative results.

It is well to support research and teaching on a high plane, but certain concentration so necessary to business success will not go amiss in the schools and laboratories. The line of thought should not wander so far from the sphere of practical application as to pass like atoms in the air through the orbital strata and become lost in the universe of dreams. Until the work in

schools and colleges is conducted on a business basis—till they become self-supporting—the business men who now support them through taxes and endowments will demand a certain "hewing to the line."

Were the universities left to the management of un-businesslike faculties the result would be a decay of purpose throughout all departments. They would attain the condition of the inveterate bookworm who reads without plan for his own pleasure until he becomes nothing but mere dreamer and puts his life away in the library corridors, a sad example of premature senility.

This is not intended as a sermon against abstract science, but rather a plea from the lowbrow business outpost. Perhaps many of your readers, too modest or too busy to express their views, may concur in these opinions.

F. GISTON.

Analytical Control of Electrolytic Zinc Production

To the Editor of Chemical & Metallurgical Engineering

SIR:—For the benefit of those chemists who may have tried the methods given under the above title in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 22, p. 651 (April 7, 1920), I should like to present a few revisions which will simplify matters in some cases.

Analysis of Leach Solution (Unpurified).—With certain kinds of solutions it is impossible to filter the precipitate obtained with H_2S unless the solution is diluted to several volumes before making the precipitation. Copper and antimony may be determined as usual in this precipitate, or copper may be precipitated with "hypo" without much dilution.

Cadmium in such a solution is easily determined as follows: Take 200 c.c. of solution. If considerable ferrous iron is present, oxidize it in presence of acid with $KMnO_4$ from a burette, avoiding excess $KMnO_4$. Add 25 g. NH_4Cl , then sufficient NH_4OH to redissolve $Zn(OH)_2$, boil, filter by suction, and wash with warm dilute NH_4OH . To the filtrate add slowly, with stirring, enough Na_2S (3 per cent solution of crystals) to precipitate copper and cadmium, plus a little excess. Roughly, $Cu \times 3.8 + Cd \times 2.2 = Na_2S.9H_2O$. Heat to boiling, let settle about one hour, and filter by suction on Büchner funnel, using three close papers, and washing with warm dilute NH_4OH . The precipitate is treated with 25 per cent H_2SO_4 , etc., exactly as in the determination of cadmium in "Pure Electrolyte."

Analysis of Zinc Dust Precipitate.—The following short methods are applicable when the material is low in SiO_2 and the cadmium and zinc are entirely soluble in H_2SO_4 :

Copper.—To 0.5000 g. sample in small covered beaker add 2 c.c. HNO_3 and agitate until violent action has stopped. Wash cover and sides of beaker with a fine jet of water, add a small grain of $KClO_3$, and evaporate to about 0.5 c.c. Add about 20 c.c. of water, neutralize with KOH , acidify with acetic acid, add about 0.25 g. of sodium ammonium phosphate in 20 c.c. of water, and finish by the iodide method.

Cadmium and Zinc.—To 0.5000 g. sample add 40 c.c. of water, 6 c.c. H_2SO_4 , and a few drops of HCl . Heat to boiling, add a drop of dilute platinum chloride, and boil about two minutes. Cool the liquid to about 40 deg. C., remove the copper as in the original method, dilute to 125 c.c., and precipitate CdS from the cold solution. The rest of the procedure is identical with the original method.

Park City, Utah.

Notes on French Industries

FROM OUR SPECIAL CORRESPONDENT

PARIS, France, Feb. 15, 1921.

THE subject of nitrogen fixation is now occupying a prominent place in French financial and industrial circles. The Compagnie Nationale de l'Azote (National Nitrogen Co.), recently founded and capitalized at 12,500,000 f., hopes to obtain a license for the Haber process, which, as reported in CHEMICAL & METALLURGICAL ENGINEERING of Nov. 17, 1920, p. 956, was bought by the French Government for 50,000,000 f. from the Badische Anilin- und Soda-Fabrik; but this license privilege will require the sanction of the French Parliament. In the meantime the shareholders of the company have voted an increase of capital to 20,000,000 f., and in addition, it is rumored, to issue bonds for 100,000,000 f. This last policy will be strongly opposed, especially by the periodical *L'Engrais*, devoted to the fertilizer industry. It is also stated that the company is intimately connected with the Société Kuhlmann, which is already using the Haber process. To complicate things even more, it is expected that in the near future patent infringement litigation will start between the companies using the Haber process and the Société L'Air Liquide (Liquid Air) which uses the Georges Claude process, based on the allegation that this last process is merely a modification of the Haber process.

FINANCIAL DIFFICULTIES IN THE CHEMICAL INDUSTRY

The Société Alsacienne de Produits Chimiques, which has recently increased its capital to 30,000,000 f., as reported in my previous letter (CHEM. & MET., Feb. 23, 1921, p. 328), is now facing great financial difficulties due to the precarious situation of the Banque Industrielle de Chine (China Industrial Bank), which is the backer of the company.

The Compagnie Nationale de Matières Colorantes (National Dyes Co.), with its new plants at Oissel and Villers, is now in a position where it can work only part time and had to close and finally abandon its model research laboratory at Suresne. It is foreseen that the company will soon be forced to increase its capital.

The Usines Chimiques du Rhone has made the announcement that it will increase its capital from 3,200,000 f. to 21,600,000 f. by issuing 184,000 100-f. new shares. The company is now producing synthetic perfumes, pharmaceutical and other organic synthetic products. It has completely abandoned the manufacture of war-time products. (During the war this company produced 150 tons of phenol per day.)

Sales of chemically manufactured products have almost completely stopped and this is a source of great concern, especially to the Union des Producteurs et Consommateurs pour le Développement de l'Industrie des Matières Colorantes (Union of Producers and Consumers for the Development of the Dye Industry in France). This union, which was created to serve as a go-between for producers and consumers, bought in Germany soon after the armistice was signed practically all the dyes it could find on the market, but it cannot sell them, so that now it has vast quantities of dyes in stock waiting for buyers.

The French Government is trying by every means at its disposal to encourage the national chemical industry and to counteract the flooding of the French market with German chemical products. The best the govern-

ment could do was to treble the import tariff for the greater part of the intermediates derived from coal tar. The list of these products which are now subjected to the new tariff was published in the Jan. 14, 1921, number of the *Journal Officiel*. The impression which prevails among the French chemical producers and especially among the dye manufacturers is that the aim of this new tariff schedule is to give to the national industry an opportunity to develop and to demonstrate whether it can resist foreign competition and subsist.

SITUATION OF THE FRENCH METALLURGICAL INDUSTRY

The Comptoir Métallurgique de Longwy, which for the last forty-five years has controlled the market of French phosphoric pig iron, was dissolved on Feb. 1, 1921. This comptoir, which comprised twenty French metallurgical companies, was forced to cease its operations due to its inability for some time past to exercise on the market a regulating and stabilizing influence as in former years and which was its *raison d'être*. This is due especially to the strong influence exercised by the new Lorraine companies, which possess great producing capacities and have yet vast quantities in stock, thus enabling them to flood the French market with their products. To this is also to be added the continuous inflow of Belgian and Great Duchy of Luxembourg products, which can be placed on the French market at prices far more advantageous than those asked for the French products.

Negotiations are now going on for the creation of a combination of French, Belgian and Luxembourg producers; it is expected that if such a combination is formed it will result in the elimination of an abnormal competition system and will put a stop to the policy of price cutting beyond reasonable limits.

FRENCH OIL SHALE

The increasing demand for oil and the continuous increase in its cost contribute to a serious consideration of giving an impetus to the French shale oil industry. Although France has extensive deposits of oil shale, especially around Bussières and Autun, very little attention has been given to this important material and at present there is only one oil shale-distilling plant of importance in all France. This plant is situated at Seyssel (Department of Ain) and produces annually about 100,000 hl. of oil (about 2,500,000 gal.), necessitating the treatment of about 200,000 tons of shale. The Scotch type of retorts has gradually displaced the older iron vertical retorts. The density of the oil is between 0.870 and 0.900; it contains about 5 per cent light oils of 0.730 to 0.750 density and about 30 per cent of oil of 0.810 to 0.850 density, the remainder being heavy oil used generally for manufacturing oil gas; the coke residue amounts to about 2.7 per cent. The greater part of the 0.850-density oil is used for lighting and a small part of the 0.875-density oil serves as a solvent for the extraction of alkaloids from quinine. The gas is used partly under the retort and the remainder, after washing and purifying, is used for lighting. In addition the Seyssel plant is producing about 10 lb. of ammonium sulphate per ton of shale treated.

The oil-shale industry, which up to 1914 subsisted only with difficulty, has since then grown steadily, and it is expected that in the near future the production will be trebled. Plans are now under consideration for the development of the French oil-shale deposits.

Swain's Report on Smoke in Salt Lake Valley

Summary of Field Conditions Surrounding Murray and Midvale Smelters and the Resulting Effect on Plant and Human Life — Notes on Operating Conditions Giving Immunity From Damage and Difficulties in Stipulating Maintenance Without Hampering Progress

IT MAY be recollected that during February, 1920, Federal Judge Johnson decided a smoke suit against the American Smelting & Refining Co. and the United States Smelting, Refining & Mining Co., allowing their smelters at Murray and Midvale respectively to continue operations under certain conditions and under observation of a staff headed by Prof. R. E. Swain of Leland Stanford University.¹ Prof. Swain, acting as commissioner, was to report his findings to the Judge after one year, this report to form a basis of a permanent stipulation as to methods of smelter operation whereby no nuisance or damage in the surrounding country would result.

After a year's research by eight assistants the commissioner has presented an exhaustive report, containing about 500 typewritten pages and many plates and photographs. A summary of his conclusions of general interest follows:

CONDITIONS AT MURRAY

The evidence appears to be conclusive that the plant of the American Smelting & Refining Co. at Murray was not at any time during the period of this investigation an agent of injury to crops or to vegetation of any kind, or the cause of personal discomfort or ill-health to the residents of that district.

Dr. Pool was in residence here without interruption from May 3 to Sept. 8. It is his expressed opinion that there was no damage whatever by sulphur dioxide even to the extent of questionable foliar markings on the most sensitive plants in the Murray district during the period of his residence here. My own observations are in entire agreement with those of Dr. Pool.

CONCENTRATION DANGEROUS TO PLANT LIFE

A study of the record of the atmospheric analyses made on the Murray smoke stream reveals no series of consecutive determinations, nor any average concentration for an hour or more, at any point in that district which, under critical weather conditions, would give rise to undoubted injury to sensitive vegetation. During the growing season—from May 2 to Oct. 19—4,386 determinations of sulphur dioxide were made on the air of this district at locations which were as nearly as possible in the line of movement of the roaster stack gases. When proper allowance is made for the probable analytical error in the method employed as determined by the control tests which were made at intervals during the investigation, none of these determinations shows an hourly average of more than one part per million. Even under weather conditions most favorable to sulphur dioxide action on the more sensitive crops, injury may not be expected to arise from any maximum hourly average obtained in this field. Owing to the changeable

character of the wind in this section, it rarely happened that a series of determinations could be continued at one station for more than one hour with any reasonable expectation of getting positive results.

It is now generally conceded that a concentration of at least one part per million over a period of three hours is necessary to produce undoubted injury to the more sensitive crops. It will require a concentration of at least 1.3 parts per million if the period of fumigation were reduced to one hour. From either viewpoint, there is not in this record, even in the highest hourly averages found and an assumed coincidence of critical weather conditions, any proof that the more sensitive crops of the Murray district were subject to injurious action by sulphur dioxide at any time during the season of 1920.

CONCENTRATION CAUSING NUISANCE TO HUMANS

The question of whether the waste products discharged from the exit stacks of the Murray plant are injurious to the health or a substantial menace to the comfort and happiness of the residents of the district must be approached from another direction. Fortunately, reliable scientific data are at hand, as a result particularly of the work of the Selby Smelter Commission, bearing on the subject of the local and immediate physiological reactions which are induced by the breathing of air containing sulphur dioxide. The average human adult, who is already acquainted with the odor of this gas, will first be able to detect it at a concentration of 3 to 3.5 parts per million.

The average person not well acquainted with the smell could detect the gas at a concentration of from 4 to 5 parts per million. Above 5 parts the presence of the gas is increasingly apparent until at 10 parts per million the action is usually sufficient to cause most subjects to feel slight discomfort or to cough. Further results of that study, based on observations made on sixty subjects, are that occasional short whiffs of less than 5 parts per million certainly could not be considered a nuisance to anyone; long-continued breathing of air containing slightly more than 5 parts per million would probably cause discomfort to most people, although occasional momentary whiffs of 5 to 10 parts per million would not be disagreeable; and a few breaths of 10 parts per million would probably be called a nuisance by most people, even if this were present only at considerable intervals.

A survey of the entire record of atmospheric tests in the Murray district, amounting to 5,923 single determinations, shows that only nineteen of these represent a concentration of 3 parts or more per million, and only one a concentration of 6 parts per million. The highest concentration ever found in this district was 7.6 parts per million. These higher readings were in all cases preceded and followed by much lower readings. In

¹See "Smoke Litigation in Salt Lake Valley," CHEM. & MET. ENG., vol. 22, p. 1145, June 23, 1920.

other words, they represent momentary "puffs" of smoke, running much higher in sulphur dioxide, which are occasionally noted especially on days of gusty winds. No other conclusion is possible than that the concentrations of sulphur dioxide which occurred in the Murray district during the period of this investigation could not possibly be regarded as a nuisance or an actual cause of notable physical irritation or discomfort to the residents.

GROUND GAS

The contamination of the air in the immediate neighborhood of the plant through leakage of sulphur dioxide from furnaces and flue systems is relatively slight. These so-called "ground gases" or "low-down gases" have often been the cause of justifiable serious complaint by persons residing very near to smelters in other sections of the country. Certain of the older types of roasting furnace were especially hard to control in this respect, back drafts would often occur, and high concentrations of sulphur dioxide would escape directly into the air at the ground level. Although often of high concentration, these low-down gases, with furnaces of modern design, as a rule represent small volumes and rarely travel far from the point of discharge at an objectionable concentration, owing to the rapid absorption of the sulphur dioxide by the soil. At both of the plants concerned in this investigation precautions have been taken to prevent the discharge of furnace gases except through the exit stacks.

Both plants employ the Dwight-Lloyd and the Wedge type of roasting furnaces. The amount of leakage from these furnaces is small, owing to their construction and to the good draft maintained, and the products of combustion are swept away under induced draft into the main flue system. The blast-furnace building at each plant is well ventilated, and points where objectionable waste products may escape are hooded and the emanations are swept out into the ventilating flue.² At the Murray plant the ventilating flue leads to a large brick settling flue where the velocity of the gases is very low, and finally enters the roaster flue near the base of the 455-ft. stack. At the Midvale plant the ventilating gases are conducted to a small bag house, filtered to remove suspended solids, and thence discharged into the air. There is a small loss of sulphur dioxide from the bag house at each plant, especially during shake-down and other periods. This is greatest at Midvale, in the roaster section of the bag house, where the concentration of the sulphur dioxide is (0.70 to 0.85 per cent) much higher than it is in the section which handles the blast-furnace gases (0.01 to 0.05 per cent sulphur dioxide).

LEAD AND ARSENIC LOSSES

The results of the filtration tests at the Murray plant point to an average daily loss from roasting operations through the 455-ft. stack of approximately 90 lb. of lead and 120 lb. of arsenic. These figures are probably fairly representative of the efficiency of the Cottrell process of electrical precipitation, with only two units in operation at one time. There is no evidence that the above losses of lead and arsenic are objectionable. The amounts of arsenic found in the vegetation of near-lying areas are small, and even these are undoubtedly

due in part to the prevalent arsenic in the soils of the valley.

PRECISE EXPERIMENTS ON SOOT FALL

It was our intention to find out much more accurately than would be possible from the analyses of plant samples what the actual atmospheric precipitation of arsenic and lead is in this valley by collecting snow samples by skimming the surface at various locations to a depth of $\frac{1}{2}$ in. over an area of 25 sq.ft. after a heavy snowfall. Then at as long an interval as possible thereafter without the interference of thawing or another snowfall it was planned to make a second collection of samples. The difference in the arsenic and lead in the control and the ensuing test samples would give a fair basis for estimating the amounts of these substances which are thrown into the air by industrial establishments and residential coal burning. With the country blanketed by snow, soil dust would be excluded quite perfectly. By studying the result in relation to wind prevalence and velocity it was hoped that data of real value would thereby be secured.

Unfortunately, there has been no time this winter when a fall of snow has not been followed within twenty-four hours either by another snowfall or by a rapid thaw. It was planned early in the investigation to expose vaselined plates at various stations as a means of approach to this question, but this was abandoned in view of the fact that wind-swept dust from the soil could not be excluded by this proposed method.

But even in the absence of more exact data than those based on the analyses of exposed vegetation, there can be no reasonable cause for concern over the discharge into the open atmosphere, at a considerable height, of the above amounts of arsenic and lead in such a state of extremely fine division as these escaping dusts represent. I am confirmed in this conclusion by an experience with another smelter from which the stack loss of arsenic amounted to approximately thirty tons per day, and with several cement plants from which, before remedial measures were installed, dust in amounts ranging as high as sixty to seventy tons per day was lost.

CONDITIONS AT MIDVALE

The results of the investigation lead to the unavoidable judgment that the Midvale plant has been at times during the past season, and under present conditions and methods of operation may continue to be, an agent of injury to the vegetation of the neighboring district. The conclusions reached by Dr. Pool are clear on this point. The "burns" reported by him in the Christensen, Lemich, Turner and Norwich cases were called to my attention by Dr. Pool and gone over carefully by us together. Thus in these cases my confidence in his judgment is supplemented by my own observations.

The work done by the chemists on the Midvale "smoke stream" also is indicative of a dangerous condition. Out of the 4,311 single determinations of sulphur dioxide made during the growing season, there was an average concentration of 0.49 part per million. There were twenty-eight determinations of 6 parts or more per million, the highest single determination made being 19.4 parts. There were four determinations over

²See "Tapping-floor Ventilators," CHEM. & MET. ENG., vol. 21, p. 118, Aug. 1, 1919.

10 parts per million; 153 over 3 parts per million; and 438 over 1 part per million. The highest hourly average recorded was 2.78 parts per million, there being thirty-four hourly averages giving over 1 part per million by analysis.

It cannot be denied that the more sensitive crops cannot, under weather conditions favorable to sulphur dioxide action, endure such concentrations as have been found in this field. On the other hand, the results hardly justify the finding that the sulphur dioxide in the gas stream from the Midvale plant is the cause of actual discomfort to the residents of the district. There were momentary concentrations sufficient to cause coughing and local irritation, but only four determinations in all the time spent in the gas stream making tests were above 10 parts.

All results on filtration tests at the Midvale plant point to the efficient operation of the bag house units through which all flue gases are passed. The average daily loss in lead and arsenic is certainly too small to be a source of any possible injury to the animal life of the district.

REMEDIAL STEPS

It is my belief that steps should be taken by the United States Smelting, Refining & Mining Co. as soon as possible to improve the situation in regard to atmospheric concentrations of sulphur dioxide during the season of plant growth. The best means for accomplishing this end, in my opinion, lies in increasing the temperature of the roaster gases before their discharge into the air. No measure approaches this one in relieving an unfavorable field condition. I believe that a solution of the matter at the Midvale plant may be found without going to the expense of the suggested erection of a 450-ft. stack in addition to heating the gases.

SAFE OPERATING CONDITIONS

It is my firm opinion that if the Murray plant is continued under skillful management, if attention is paid to keeping the bag house and the Cottrell plant at their highest practical efficiency, and if the general operating conditions which prevailed during 1920 are maintained, the plant will be able to operate hereafter without being an agent of injury to its neighbors. But the fact should not be overlooked that the very favorable record of the past year is in all probability due to a number of important contributing factors, most of which fortunately involve no more than the continued intelligent and consistent use of operative measures which are already at hand and a part of the routine normal operation of the plant.

The operative measures which should receive attention are:

1. The bag-filtration of the blast-furnace gases.
2. The electrical precipitation of roaster dusts and other suspended solids by means of the Cottrell installation, two of the three units of which have been in regular operation.
3. The discharge of the roaster gases, which carry the highest concentrations of sulphur dioxide, at a temperature high above that of the outside air. During the dormant season for plants the temperature of these roaster gases was increased, and incidentally their volume as well, by the delivery of the boiler gases from a neighboring power house directly into the main exit stack. During the season of plant growth the

gases were heated by means of coal furnaces near the base of the stack.

4. The discharge of the gases from roasting operations from a high stack at a point approximately 455 ft. above the ground level.

5. A maximum daily elimination of sulphur from roasting operations amounting to about 100 tons.

Industrial plants such as this are complicated and sensitive organisms. They will not run themselves. Their successful operation from the standpoint of a high recovery of metal at a low cost of production requires that painstaking attention be paid to all factors which have to do with the efficiency and cost of smelting operations. The situation is not now different in regard to smelter operation in relation to smoke injury. With the recent development of remedial measures having to do with plant operation a new responsibility has been thrust upon the operating staff, a responsibility which calls for no less skillful and painstaking attention on their part.

It can scarcely be denied that this plant is a potential agent of injury. Allow the filtration bags to deteriorate, reduce the voltage in the Cottrell plant, neglect the measures which have to do with maintaining a relatively high temperature in the exit gases, and a discharge of lead and arsenic in objectionable amounts or of sulphur dioxide under conditions of concentration and temperature which could give rise to serious injury to crops might easily result.

GUARANTEES AND RESTRICTIONS

At once the question arises of what reasonable guarantees should be exacted, or what operating restrictions or other stipulations imposed to insure the indefinite continuance of safe operation. At first thought it would not appear unreasonable, with a plan of plant operation of proved safety before us, to make this the basis of future operation. This should at once give adequate protection to the residents of this community, but it has several serious objections. In the first place, as has been pointed out, there are many phases of plant operation involved as contributing factors to the present condition of immunity from damage. These are not so much independent as they are interdependent.

Thus it is no longer wholly logical, as a single measure of protection, to place a restriction on the amount of sulphur eliminated or the tonnage of ore roasted when it is known that by a suitable change in one or more other factors, such as the temperature of the exit gases, double that amount might be eliminated with even greater assurance of immunity from trouble. Accordingly, if stipulations are drawn up along the line of plant operation, they must deal not with one but with a number of factors and to that extent be more or less complicated. There is another objection to this proposal which is more serious. These are days of industrial progress based largely upon a new relation between science and industry. Rule-of-thumb methods are yielding to more intelligent and progressive direction. A set of stipulations dealing with plant operation, such as mentioned above, are at once a barrier to progress. Until changed, they may be just as effective in preventing the introduction of improved methods of operation as they are in preventing a relapse into a condition which makes plant operation a menace to the community.

Phosphoric Acid Evaporation

Description of a New Method for the Evaporation of Phosphoric Acid Without the Formation of Scale in the Apparatus During Operation—Accomplished Without Raising the Temperature of Liquid to Ebullition Point

By H. E. LABOUR

THE early manufacturer of phosphoric acid used bone char or its equivalent as a source of phosphate supply. The phosphoric acid was readily extracted from this material and the process of purification was simple. In order to concentrate phosphoric acid made from bone, ordinary steam-jacketed kettles or open pans were most commonly used, and aside from the necessity of properly protecting against the corrosive action of the acid itself, very little trouble was encountered. The acid carried only a small amount of scale-forming material and the volatile impurities were not so annoying that evaporation could not be carried on safely in an ordinary plant.

The supply of bone char did not increase in proportion to the demand for phosphoric acid and phosphates, and this led to the use of phosphate rock as a substitute source of supply. The purification of phosphoric acid as made from rock brought in different and much more difficult problems than were encountered when bone was used. Impurities were introduced into the acid which required elaborate and careful means for removal, and in the process of removing these impurities it frequently happened that others were introduced so that the liquid, by the time it was ready for concentration, carried a very high percentage of scale-forming material, as well as highly corrosive volatile materials, the most troublesome of the latter being fluorine.

Up to the time of the active production of double superphosphate, the difficulties already mentioned were mostly those encountered by manufacturers of food phosphates, and as the production of the material was limited in this country to a few concerns, the problem of evaporation of phosphoric acid was not given the thought and attention which it should have received.

DIFFICULTIES ENCOUNTERED IN THE USE OF COMMON TYPES OF EVAPORATORS

As soon as the fertilizer manufacturer attempted to concentrate his phosphoric acid, he found that the evaporation constituted a real problem, and many different methods were proposed and tried for this work. The vacuum evaporator was early given consideration due to its high economy of operation, but two distinct troubles were encountered which were never satisfactorily overcome. The first of these was the kind of material to be used for the parts coming in contact with the acid or the vapors. About the only metal which successfully withstood the acid was lead, and to make the matter still more serious, lead had to be used for all of the vapor fittings also, on account of the liberation of fluorine during evaporation. Even assuming that these difficulties could have been overcome, the second problem would have made the use of a vacuum evaporator entirely out of the question. The

acid as delivered to the evaporator carried in solution a very high percentage of scale-forming materials such as calcium sulphate, and as soon as concentration began these were deposited on the heating pipes or surfaces and would sometimes build up to as much as $\frac{3}{4}$ in. thick in the course of a 12-hr. run. This heavy scale materially reduced the economy of operation and introduced the frequent cleaning factor, making the vacuum evaporator an impracticable unit for this work.

Various atmospheric methods of evaporation were also in service, such as troughs or pans having submerged steam pipes, or which were heated by hot gases, or even direct fire. These had the advantage of simplicity, but were low in economy, and the scale-forming trouble was always present.

Much work has also been done in connection with the use of towers, both packed and open. The packed tower gives a much better distribution of acid and of the hot gases, but the packing accumulates scale and sludge pockets, and the tower requires frequent cleaning. Furthermore, if hot gases are used as the means of evaporation, an entirely different trouble is encountered—namely, the formation of metaphosphate, which hangs up on the packing and tower walls as a rather sticky material. The sludge from the upper part of the tower gradually works down and accumulates with the metaphosphate formation until finally a hard, tough coating is formed. This is extremely difficult to remove, and of course the metaphosphate represents an actual loss. The open tower had the advantage of offering less surface for accumulation of sludge or scale, but the metaphosphate was still formed and frequent shut-downs resulted.

SPRAY EVAPORATING SYSTEM

In studying this problem, the writer decided that in order satisfactorily to solve the problem of construction materials, it would be necessary to make the evaporating unit of as small dimensions as possible, especially those parts coming in contact with the acid, and, to reduce the corrosion difficulties as well as to eliminate the chance of formation of metaphosphate, evaporation should be carried on without raising the temperature of the liquid to ebullition point. It was recognized that it would be perfectly safe to heat the liquid to some temperature below that producing ebullition and still get no scale formation, as it was quite obvious that the scale formation was due to the deposition of sludge on the heating surfaces, and formation of the sludge was in turn due to the concentration of the acid. If, then, the acid was merely heated and not evaporated by contact with hot surfaces, there would be nothing to cause the formation of scale. If part of the heat that had been introduced into the acid could be utilized converting it into latent heat of

vaporization, out of contact with any heated surface, the scale-forming materials should come down as a sludge and should wash out with the acid as long as the whole body of material was kept in motion.

The use of a spray machine producing spray by throwing the liquid from the surface of a revolving disk seemed ideally adapted to this work, and experiments were carried on to determine the feasibility of the process. The experiments were successful, and the process has now been thoroughly worked out.

The accompanying drawing shows the general arrangement used in this method of evaporation. A heating tank having two concentric compartments is used. The outer or annular one of these has a partition which converts it into a circular trough, and in this outer compartment are placed steam coils. The weak acid is delivered to this circular trough on one side of and immediately adjacent to the dividing partition, and also on this same side of the partition is a large

practically the same, the only difference being in the relative humidity. The latent heat of vaporization is supplied by the acid and the temperature of the exit acid is consequently considerably below that at which it entered the spray machine. Also the scale-forming material comes down as a sludge, and having no hot surfaces on which to cling is washed out of the spray machine and is carried along with the acid. If the amount of scale-forming material is particularly heavy, a settling trap should be introduced between the machine and the center compartment of the heating tank.

The center compartment of the heating tank is also provided with an overflow pipe at the maximum liquid level and a portion of the finished acid is discharged from this constantly; the volume of this discharge being, of course, a factor of the volume of weak acid supplied and the amount of water evaporated. The remaining and greatest bulk of the acid delivered to the center compartment passes through the communi-

PHOSPHORIC ACID UNIT EVAPORATOR

submerged communicating opening between the inner and outer compartments. The weak acid, together with a certain amount of strong acid from the inner compartment, flows around this circular trough and is heated to the required temperature. On the opposite side of the dividing partition from that on which the weak acid is delivered is a large outlet at the bottom, and connected to this is a centrifugal pump. This pump draws the hot acid at the required rate and delivers it to the spray machine. Here the acid is thoroughly atomized and brought into contact with conditioned air. Evaporation of water takes place, the air in passing out carrying away the water vapor together with practically all of the fluorine content, and the concentrated acid passes out from the bottom of the machine to the center compartment of the heating tank. The temperature of the ingoing and outgoing air is

cating opening between the two tanks, and joining the weak acid, is again passed through the spray. The function of recirculating this large volume is twofold: first, to supply sufficient heat units for evaporation, and second, to insure the elimination of fluorine.

A standard size unit is used. This size is ordinarily rated in terms of the number of pounds of water it will evaporate per minute from the acid. This rating usually remains unchanged regardless of the initial or final strengths of the acid to be handled.

As an example of the operation of this equipment, assume a weak acid of 19 deg. Bé. to be concentrated to 40 deg. Bé. Also assume a desired rate of evaporation of 35 lb. of water per minute. Deliver to the spray 150 gal. per minute of acid at approximately 40 deg. Bé., and at a temperature of 220 deg. F. allowing for radiation losses, the temperature drop will be approximately 38.6

deg. F., or the exit temperature of the acid will be approximately 181.4 deg. F. Assuming that air fully saturated at 160 deg. F. will carry the proper amount of moisture when the exit volume of the gas mixture equals 3,000 cu.ft. per minute, then allowance must be made for an actual exit temperature of something in excess of 160 deg. F. on account of the partial vapor pressures existing in the system. In this case the actual exit temperature would have to be in the neighborhood of 175 deg. F. In order to insure maximum evaporation with a minimum time of contact, it is advisable to preheat the relatively dry incoming air to approximately the same temperature as that at which it will leave the spray.

Assuming that the rate of feed of weak liquor to the heating tank is approximately 10 gal. per minute, and the rate of delivery to the spray is 150 gal. per minute, then the remaining 140 gal. per minute must be recirculated and delivered to the heating compartment from the inner or settling compartment. This 150 gal. per minute would pass to the spray, where there would be, roughly, 4 gal. per minute of water removed, and 146 gal. per

minute of concentrated acid returned to the center compartment of the heating tank. Since only 140 gal. of this has to be recirculated, the remaining 6 gal. would pass off from the overflow pipe as finished product. It will be noted that any change in the rate of feed of weak liquor will automatically change the rate of exit of finished liquor, and consequently the concentration, so that the entire control of the apparatus once it is in operation is carried on by means of the valve controlling the supply of weak liquor.

If all power, both steam and mechanical, be converted to a steam basis with the best of the pan or submerged type of evaporators 1 lb. of steam will evaporate only approximately 0.5 lb. of water and as the scale formation increases even this rate of evaporation is reduced. With the spray evaporator radiation losses are materially reduced and the heat transfer is handled in a much more efficient manner; consequently, the economy obtained is approximately 0.65 lb. of water evaporated per lb. of steam condensed. This economy of evaporation holds uniform, as scaling trouble is not encountered.

More Flakes

BY HAAKON STYRI

IN THE issues of CHEMICAL & METALLURGICAL ENGINEERING for April 1 and May 1, 1919, the writer discussed several types of flakes, their occurrence and possible elimination.

Recently a particular type of flake has come to the writer's notice of which there can hardly be any doubt as to the origin. We had found a number of flakes in a 4½-in. bar of high-carbon chromium steel and wanted to investigate this trouble further. For that purpose thirty-one disks about ⅜ in. thick were cut from an annealed bar. All these disks were treated with gasoline containing fine grinding chips of steel. It was found that Nos. 1 to 17 inclusive contained cracks and that Nos. 18 to 31 inclusive did not reveal any.

Disks 11 to 15 inclusive were bent slightly and it was found that they contained more cracks than were found with gasoline treatment only.

By fracturing disks 16 and 17 it was found that the structure where the flakes opened was coarser and more crystalline than the surrounding normal material.

Disk 2 was examined microscopically where a crack had shown up with gasoline, but no crack could be found even under 1,000 magnifications after the piece had been

polished and etched with 1 per cent nitric acid in alcohol, but the crack was revealed with deeper etching.

Two disks, 18 and 20, which had not shown cracks with the gasoline treatment, revealed cracks in bending.

Eighteen disks, 3 to 10 inclusive and 20 to 29 inclusive, were now hardened and thereafter fractured. All these showed flakes and in disks 3 to 10 inclusive they were found to correspond with the cracks located with gasoline before hardening. Some additional flakes also appeared. The structure of these flakes after fracturing had the same coarse crystalline appearance as the structure of the flakes found in bending the unhardened disks, but outside the flakes the structure was fine and silky.

Several streaks were found in the flakes, probably manganese sulphide, but sulphur prints did not reveal the presence of more sulphide in the flakes than other places in the fracture. Some of the flakes found extended through the whole thickness of the disks, even where no flakes had been located with the gasoline treatment, and were from ⅛ to ⅙ in. long. All the flakes found were parallel to the direction of rolling, and were comparatively flat.

It seems evident that these flakes were produced during rolling and not by any heat-treatment of the bar.

Refinery Practice in Beet Sugar Manufacture

Description of Modern Practice in the Beet Sugar Refinery—Purification of the Diffused Juice by Precipitation of Lime Carbonate and Filtration—Evaporation in Vacuum Pans to Massecuite—Treatment of Sirup and Sugar

BY WALLACE MONTGOMERY

THE first step in the sugar recovery process is to heat the raw juice. This is done with exhaust steam or vapors from the evaporators. The temperature of the juice entering the heaters is about 55 deg. C., depending, of course, upon the temperature carried in the battery. The juice leaving the heaters should not be less than 80 to 85 deg. C., as it has been found that the saturation of the juice with CO_2 is best carried on at about 80 deg. C. From the heaters the hot raw juice is pumped to what are known as carbonation tanks. The tanks may be of any shape, though the ones in general use have quite a slope in the bottom allowing free discharge. In the bottom of the tank is some form of distributor for the gas, either a perforated coil or a long box, inverted, with saw-tooth edges allowing the escape of the gas on all sides.

The raw or diffusion juice from the beets varies in quantity from 125 to 160 per cent on the weight of the beets and is of approximately the following composition:

Brix, deg.....	12.50	to	15.00
Specific gravity.....	1.0506	to	1.0613
Sugar, per cent.....	11.5	to	13.50
Purity.....	82.00	to	85.00
Ash, per cent.....	0.55	to	0.65

PURIFICATION OF THE BEET JUICE

It is now essential that the juice be purified or defecated. This is accomplished by the addition of lime solution. In a factory not using the Steffens process of recovery of sugar from the waste molasses, milk of lime alone is added at carbonation, but in a factory that has a Steffens house in connection, the lime is added in the form of a lime-sugar combination or saccharate. The burning of the limestone is accomplished in large vertical kilns.

The hydrated burned lime reacts with the salts present in the juice and neutralizes any acids present. A heavy precipitate is formed upon addition of CO_2 , and the lime is again converted into CaCO_3 . As the precipitate settles out there is some mechanical purification.

In a refinery not using the Steffens system the addition of from 3 to 3.5 per cent of lime, based on the percentage of beets, is sufficient. In a Steffens house from 4 to 6 per cent is added, depending upon the speed of working and the impurities present. The control of the carbonation is of utmost importance. It is carried on until the juice has an alkalinity of from 0.085 to 0.110 g. CaO in 10 ml. This partly treated juice is again pumped through heaters, the temperature being raised to 90-95 deg. C., then pumped through some form of filter. In some factories the plate and frame type is used. Work is now being done on a continuous filter for this purpose and shortly it will be in use.

From the presses a clear liquid of light straw color is obtained. In the presses the precipitate, or lime cake, as it is called, remains. This cake contains considerable

sugar, removed by washing with hot water. The quantity of cake varies with the process, but usually amounts to from 40 to 48 lb. per ton of beets sliced.

Wash water to the extent of from 30 to 40 per cent of the weight of the beets, lime approximately 4.5 per cent and CO_2 from 3 to 4.5 per cent is used, bringing the total volume of juice up to about 200 to 220 per cent on the weight of the beets.

From the first presses the juice goes through another heater and is raised to about 95 to 96 deg. C., precipitating any salts or combination of salts that are still present from the first saturation. From these heaters the juice is again filtered and then passes to the second carbonation or saturation tanks. Here the procedure is much the same as in the first carbonation, only no lime is added. The juice is gassed until it contains only 0.025 to 0.030 g. CaO per 10 ml.

INVERSION REDUCED TO MINIMUM

The addition of a solution of soda ash here has been found beneficial in further reducing the lime salts present in the juices. Soda added up to 2 lb. per ton of beets worked will be found beneficial, though an excess will tend to increase the inert sugar content. In all cases the amount should be strictly governed by determining the lime salts present by titration with standard soap solution and holding the juice at 0.030 to 0.045 g. CaO per 100 ml.

Further heating and refiltration give a clear straw color juice, known as second carbonation juice. The addition of SO_2 is usually the next step. Here the alkalinity is reduced to approximately 0.010 to 0.012 g. CaO in 10 ml., after which the juice is filtered again, and the resulting juice, known as thin juice, amounts to approximately 220 to 240 per cent of beets and is of the following composition:

Brix, deg.....	12.0	to	14.0
Specific gravity.....	1.048	to	1.057
Sugar, per cent.....	10.00	to	12.00
Purity.....	85.0	to	88.0
Ash, per cent.....	0.85	to	1.15

The juice is now ready for evaporation, which is carried on under vacuum in multiple effect evaporators, of which there are numerous types and makes.

The juice is concentrated to from 55 to 60 deg. Brix and is sent to the melter to mix with the raw sugar or sent direct to heating tanks, heated, filtered and sent to vacuum pans, where crystallization is carried to completion.

PREPARATION OF THICK LIQUOR

When the juice goes to the melter raw sugar amounting to from 4 to 6 per cent of the weight of the beets is added, making the thick juice amount to 46-48 per cent of the beet weight.

A further sulphuring is usually made here, reducing the alkalinity, which, due to concentration, is about 0.060 to 0.075 g. CaO to 10 ml., down to 0.010 to 0.012 g. CaO in 10 ml.

In a series of experiments by the writer the following results were obtained:

Sample	D.S. by Refract.	Color to 100 D.S.	CaO to 100 D.S.	Alk. to 100 D.S.	
1	63.0	60.2	0.206	0.216	Before SO ₂
2	62.0	65.4	0.266	0.222	
1	63.0	40.0	0.119	0.013	After SO ₂
2	62.05	50.8	0.129	0.032	
Per Cent Reduction of Color			Per Cent Reduction of CaO		
1		33.4		42.2	
2		22.3		51.5	

This shows that for reduction in color the alkalinity should be 0.010 to 0.012 g. CaO per 10 ml., but for greater reduction of lime salts 0.030 to 0.040 g. CaO per 10 ml. gave best results.

FIRST LIQUOR

The evaporator thick juice, after having been mixed with raw sugar, is called first liquor and is approximately of the following composition:

Brix, deg.....	60	to	65
Specific gravity.....	1.289	to	1.319
Sugar, per cent.....	55	to	58
Purity.....	87	to	91

and amounts to 45 to 48 per cent on beets.

This liquor is sent to tanks known as blow-ups, which are nothing more than heating tanks. Here the temperature is raised to 95 to 98 deg. C. and kieselguhr is added at the rate of 0.50 to 0.75 lb. per ton of beets worked.

The kieselguhr acts as a filtering medium in the filter presses, through which the hot liquor is pumped.

FIG. 1. VACUUM PANS

The resulting clear, light-colored liquid is now ready for graining. The graining is accomplished in vacuum pans. Fig. 1 shows one type. The proper control of the crystallization requires experienced operators or sugar boilers.

The principle of graining consists of evaporating the liquor or sirup until such a concentration is reached that the crystals of sugar form, after which more sirup is added and evaporation continued successively until the operator has finished the pan or strike.

There are many methods of graining a pan besides the above-mentioned, one of which is the adding of sugar powder or dust to the saturated or nearly super-

FIG. 2. CROSS-SECTION OF SUGAR CENTRIFUGAL

saturated solution. The point of supersaturation varies with the purity of the juice. A higher purity or purer juice will form crystals at a lower point of supersaturation than one of lower purity. By the sugar powder method a more uniform grain is formed, which means a higher yield and a slight saving in steam consumption, due to time gained in graining.

MASSECUITE CENTRIFUGED

The sirup having been boiled to grain, the first massecuite, as the product of these first pans is called, is sent to the centrifugals. Fig. 2 shows a common type. The liquor coming off is called green sirup. This is the liquor that has not formed any grain in the pan while boiling the first strike. The purity of the green is about 72 to 75 and the quantity is approximately 22 to 25 per cent, based on beets worked; the massecuite amounts to approximately 46 to 50 per cent of the beets.

Some green sirup stays in the centrifugals with the crystals and later has to be washed out. This is where the wash sirup is obtained. In the case of very fine crystals the wash purity will probably go higher than the original purity of the pan on account of some of the grain dissolving. In a coarse grain strike there is less danger of this happening. So from the liquor originally boiled we have

	Purity
Green sirup.....	72 to 75
Wash sirup.....	84 to 89
Sugar.....	100

We still have the green and wash sirup to contend with. The wash is sent to blow-ups as was the first liquor, where it is heated, sulphured and filtered, though only 0.25 to 0.35 lb. of kieselguhr per ton beets worked is used on this sirup. The filtered solution is sent again to the pans, where it is drawn in with the first liquor and reboiled. The green is similarly treated, but being of such low purity it is impossible to make white sugar from it directly; therefore it is boiled separately and put in crystallizers, Fig. 3 showing the open type, where it is allowed to remain for 72 to 96 hours, in which time the size of the crystals increases, due to the cooling of the supersaturated solution. It is then centrifuged and we have a similar condition as with the first pans, although the purities are much lower, the green from the second pans or raw pans being 60 purity or less, while the wash water, only sufficient being added to remove the green, runs about 62 to 65 purity.

STEFFENS HOUSE

It would not be possible to use these liquors for the recovery of sugar in the pans, due to the amount of impurities present. If they were boiled blank—that is, concentrated almost to the point where crystals should form and then placed in tanks or crystallizers and

FIG. 3. CRYSTALLIZER

allowed to cool—grain would form, but the yield would be very low and the sugar of low purity. Therefore these final sirups, low green and low wash, are sent to the Steffens house for the recovery of sugar from the molasses by another method. This process will be taken up in another article later on.

DRYING THE GRANULATED SUGAR

The white sugar from the centrifugals, containing about 2.5 to 3.5 per cent moisture, is sent to driers or granulators, usually in two steps, one above the other. The sugar enters one end and as the drum revolves is worked toward the farther end, while hot air is pulled through the drum by means of an exhaust fan. Figs. 4 and 5 show in a general way this type of apparatus. From the granulators the sugar, containing about 0.10 to 0.15 per cent moisture, is bagged and ready for market. The raw sugar is melted and mixed with thick juices, as we have seen before.

QUANTITY AND QUALITY TABLE

From the accompanying table some idea may be gained of the quantity and analysis of the products in the order of their appearance in the process. These figures are only approximate and vary considerably in some factories.

The term purity is best explained by an example. If we speak of a molasses of 60 purity we mean that 60

QUANTITY AND ANALYSIS OF PRODUCTS

Name	Per Cent on Beets	Brix, Deg.	Sugar, per Cent	Purity
Beets	100		16-18	79-86
Diffusion juice	130-150	12.5-14.5	10-12	82-86
Saccharate milk	60-65	30-35		84-89
Total lime used	4-6			
Juice of first carb.	210-225			
Lime cake	20-25		0.20-0.35	
Thin juice	225-250	12.5-14.0	10-12	85-89
Thick juice	40-44	55-65	50-54	85-89
First liquor to pans	45-48	58-65	52-55	86-91
First wash at high	18-22	60-65	50-55	82-88
First massecuite	48-50	92-95	78-82	86-90
White sugar	15.5-17.5		99.7-99.85	100
First green or high green	20-25	60-65	48-52	73-76
Raw pans or second mass	15-18	95-97.5	64-70	73-76
Molasses (low green)	4.5-6.5	82-87	48-52	57-62
Molasses (low wash)	1.5-2.5			
Raw sugar	5-6	95-97	92-94	95-98

FIG. 4. SUGAR DRIER

per cent of the total solids in 100 lb. is sugar. By Brix we mean the per cent solids in the solution. Therefore sugar divided by Brix or solids equals purity.

CALCULATION OF THE GRANULATED EQUIVALENT

To determine the amount of sugar recovered from the beets we must take stock of all products in the factory, measuring carefully all tanks and containers and sample each substance. Then by the following formulas we may calculate the amount of sugar to be expected from

FIG. 5. GRANULATOR

the stock in house. This is called the granulated equivalent, or

- (1)
$$\text{Granulated equivalent} = \frac{\text{Pounds dry substance or solids} \times \text{Average purity stock} - \text{Purity final molasses}}{100 - \text{Purity final molasses}}$$
- (2)
$$\text{Sugar in molasses in stock} = \frac{\text{Total pounds sugar in stock} - \text{Sugar crystallizable or gran. equiv.}}{100}$$
- (3)
$$\text{Sugar recoverable in molasses in stock} = \frac{70 \times \text{Pounds sugar in molasses in stock}}{100}$$

FIG. 6. EXTRACTION CHART

(4) *Sugar not recoverable in molasses in stock* = *Pounds sugar in molasses in stock* — *Pounds recoverable*
 Items (1) and (3) = Total sugar in stock as granulated sugar.

Another formula for expected yield that gives results comparable to above is as follows:

Per cent yield =

$$\frac{\text{Purity sugar (Purity of stock — Purity final molasses)}}{\text{Purity stock (Purity sugar — Purity final molasses)}}$$

Multiplying total sugar by percentage obtained gives sugar to be expected.

To calculate the yield from a pan or strike the following formula is used:

$$\text{Yield in per cent sugar} = \frac{M - G}{100 - G} \times 100 \div \frac{M}{100}$$

where *M* = purity massecuite

G = purity green sirup

This formula is of comparative value only as we assume sugar to be 100 purity and do not take into consideration the wash sirup. Likewise if we know the sugar content of the beet and purity we may calculate the yield by curves plotted on this basis and the assumption that total elimination beet end is 40 per cent, total known losses are 0.6 per cent, and purity of final molasses is 52 to 57 as shown by Fig. 6. This chart is applicable in a factory working only the sugar from the beets and shipping waste molasses. It does not apply to a factory having a Steffens house in connection.

The results obtained by the use of this chart will be found to check out very closely with actual work in the factory.

Fig. 6 is produced with one-fifth the scale used in a works drawing, with tenths deleted.

 Betteravia, Cal.

Draft of British Home Office Regulations for Chemical Works

Regulations applying to a wide variety of chemical processes and plants have been drafted by the British Home Office and published so that possible objections might be raised.¹ These new regulations will supersede the Special Rules for Chemical Works first established in 1894, regulations made Dec. 30, 1908, for the manufacture of nitro and amido derivatives of benzene and those made Aug. 9, 1913, for the manufacture of sodium or potassium chromate and bichromate. The manufacture of white compounds of lead and red lead, orange lead or flaked litharge is covered by separate codes. Bleaching, dyeing, mercerizing, brewing, tanning, alcohol distillation and processes carried on only by way of experiment are also exempted.

It has been recognized that in certain classes of chemical works special dangers exist which are not found in other branches of the industry and for this reason the regulations are divided into two parts, the first of which is applicable to all chemical works as defined in the schedule and the second to those only in which special dangers need to be dealt with.

Part I, applying to all chemical works, covers such items as: Providing railings on low open kettles, etc.; using an efficient exhaust draught when drawing the charge from a salt cake furnace or from a pyrites kiln, slaking lime or where arsine may be generated; enclosing mills and screens for use with lime; equipping stills and autoclaves with safety valves. The remaining sixteen clauses are devoted to an elaborate set of

hygienic measures covering mess and washing accommodation, ambulance and rescue equipment.

Part II applies to plants or parts thereof in which: Caustic pots are used; chlorate or bleaching powder is made; gas tar or coal tar is distilled or is used in any process of chemical manufacture; synthetic coloring matters or their intermediates are made; a nitro or amido process or a chrome process is carried on; shale oil is refined or used in a chemical process; nitric acid is used in making nitro compounds. In these cases the regulations relating to washing facilities are naturally more stringent and involve the supply of baths, nail brushes, soap, clean towels, etc. Protective clothing is also specified.

Certain of the hygienic features of the regulations have been criticized by the Association of British Chemical Manufacturers as being too extravagant and impracticable for introduction at a time when the financial position of the industry cannot bear the additional expense.² This is particularly true of some of the smaller and more recently established plants. While these precautions are generally recognized as absolutely essential in the manufacture of such irritants as dinitrochlorobenzene and TNT, it is feared that according to the schedule of processes included under Part II, it will be necessary to satisfy these provisions in many cases where they are not absolutely necessary. It is generally felt in the industry that had the collaboration of such a body as the above association been secured in the compilation of the regulations they would have been found more generally acceptable to all sections of the industry.

¹Copies of this draft may be obtained from the Factory Department, Home Office, London, S. W. 1.

Dust Explosions

Some Methods of Prevention of Dust Explosions—Engineering Problems Demanding Attention— Reduction of Atmospheric Oxygen Content Below Combustion-Supporting Mixture— Grounding Static Electricity

By DAVID J. PRICE

Engineer in Charge Grain Dust Explosion Investigations

IT IS now generally understood that disastrous dust explosions can occur in any industrial plant where combustible dusts are created during the operating processes. Experimental work has shown that a proper proportion of dust and air creates an explosive mixture which can readily be ignited by an external source of heat or flame. Although for some time the common causes such as open flames and matches have been accepted, the investigations of recent dust explosions and resulting fires have developed causes associated particularly with the mechanical and electrical equipment. Some of these causes relate to metallic sparks in grinding machinery and dust-collecting systems, especially in connection with the exhaust fans now in common use. Electrical causes such as broken incandescent lamp bulbs in dusty atmospheres and dust settling on the lamps have been new determinations. In addition it has been found that disastrous explosions have been caused by sparks of frictional or static electricity, and by dust ignition, resulting from the rubbing of pulleys and belts during choke-ups in elevator legs. The extent of these explosions, together with the losses caused by them, indicates the importance of the problem.

METHODS OF PREVENTION

The installation of efficient dust-collecting equipment is one of the most effective methods of controlling explosions of this nature. The accumulation of dust through-

FIG. 1. DOUBLE GROUNDING METHOD FOR CONDUCTING STATIC ELECTRICITY FROM DEXTRINE REELS

out the plant permits the propagation of flame from the time of the original ignition until the secondary or larger explosion occurs.

The elimination of open flames in dusty parts of the plant is of course very essential and should be rigidly practiced. The electrical equipment should be well protected and incandescent lamp bulbs located in dusty sections of the plant should be properly guarded. As a result of special experimental work with the lamp-manufacturing companies it is felt that vapor-proof globes would afford additional protection.

Attention should be given to the proper grounding of equipment where static electricity would be produced. This is essential in connection with pulleys, belts, grinding equipment, revolving reels and other similar types of machinery.

The entrance of foreign material into grinding machinery should be prevented by effective magnetic separators, or other devices now designed for this purpose. Special attention should be given to the prevention of choke-ups in elevator legs by systematic inspection during the operating periods.

ATMOSPHERES OF LOW OXYGEN CONTENT

Some experimental work has already been carried on in an effort to maintain an atmosphere which would not support combustion by reducing the oxygen content in the atmosphere in places where dust-laden air is unavoidable.¹ If, for instance, it was possible to maintain in a grinding machine an atmosphere which would not support combustion the dust would not ignite. The experiments conducted were for the purpose of determining to what amount the oxygen content of the air must be reduced in order to prevent propagation of flame in explosions of various kinds of dust.

The results of the tests indicate that an explosion of starch dust cannot occur in an atmosphere containing less than 12 per cent of oxygen. This limit can possibly be extended to 14 or 14½ per cent of oxygen if grain elevator dusts are considered. The maintaining of an atmosphere of inert gas in all systems grinding or handling carbonaceous materials which form dangerous dusts would, therefore, be an effective means of preventing many dust explosions. Even though an amount of dust ordinarily dangerous may be present and a spark or other source of heat may be formed, the dust would not be ignited nor an explosion be propagated, because the oxygen content of the atmosphere would be too low to support combustion.

Harger, in an article on "Coal Dust Explosion and Prevention"² states: "The only way absolutely to prevent dust explosions is to reduce the oxygen percentage below the lower limit, which varies with the different coal dusts. A reduction of 2 per cent will do for all mines, but to get a guarantee of absolute immunity 17½ per cent oxygen is the figure. A 17½ per cent oxygen atmosphere is ideal for a coal mine, if it is not too expensive to obtain, although this should not be the case."

The most easily secured inert gas around the plant is flue gas. Flue gas contains a large amount of nitrogen, 79 per cent, and the remaining 21 per cent consists of various amounts of carbon dioxide, oxygen and carbon monoxide. The results of the tests show that

¹J. Ind. Eng. Chem., vol. 9, p. 347, April, 1917.

²J. Soc. Chem. Ind., vol. 31 (1912), p. 413.

FIG. 2. CONCRETE CONSTRUCTION WRECKED BY STARCH EXPLOSION

a lower oxygen content in the inert gas mixture is probably necessary to prevent an explosion of grain dust than would be required to prevent an explosion of coal dust. The results obtained with coal dust would indicate that a lower oxygen content in the mine atmosphere than that recommended by Harger would be necessary to prevent a coal dust explosion. However, a limit of $17\frac{1}{2}$ per cent oxygen was very close to that determined in this work. As a result of the tests it has been determined that an inert gas mixture containing not over 12 per cent of oxygen will prevent a dust explosion from starting or propagating.

INERT DUST

Effective results have been obtained by the U. S. Bureau of Mines in the use of inert dusts, such as shale, limestone, etc., in preventing flame propagation. The mixture of inert dusts and air prevents the flame from propagating and has a "blanketing effect" much the same as the gauze or screen in the Davy safety lamp. Although only a limited amount of work has been done, it is felt that there is a possibility of inert dust being used in the prevention of dust explosions in mills and elevators under certain limited conditions.

It may be possible to design a method of introducing the inert dust into elevator or conveyor lines to prevent the spreading of flame from the original explosion. In numerous instances the explosion has traveled from the point of origin through the conveyor or elevator legs to bins of large capacity in which considerable dust was present. If a method of introducing inert dust could be perfected it would possibly prevent the propagation of flame and limit the explosion to small proportions.

DUST REMOVAL

In connection with dust-collecting systems as now installed in our industrial plants recent investigations have indicated that a number of explosions were directly associated with the manner in which the exhaust fan was installed in the system. In one instance a disastrous explosion of aluminum dust was caused by a piece of wire entering the exhaust fan, causing six deaths and injury to a similar number of persons. In many instances exhaust fans are installed for the removal of fine dust from buffing or polishing wheels, grinding rolls and similar equipment. In these installations as a rule the fine dust is drawn from the source of production through pipe trunkings into the exhaust fan and then blown into the collecting device. In a number of recent disastrous explosions the origin has been associated with the exhaust fan.

In installations of this nature a flammable mixture is usually formed when the dust passes through the exhaust fan. Explosions may be caused by the ignition of the dust by sparks from foreign material striking the fan blades or from the fan blades becoming loose. This situation has suggested the possibility of changing the location of the fan from its present position—namely, between the source of dust production and collection—to a position beyond the collector. In other words, can the dust be drawn into rather than blown into the collector?

The Industrial Commission of Wisconsin has designed and installed in a factory in that state a system of primary and secondary air currents for dust removal.² The commission reports that tests demonstrating the practicability of the system have already been made.

RESEARCH ENGINEERING PROBLEMS

In order to conduct a special educational campaign of dust explosion prevention both during the period of the war and until the expiration of the wheat guarantee act it was necessary for the Bureau of Chemistry to discontinue a number of the important lines of research work. Several problems are now presenting themselves for consideration indicating the necessity of further development before effective methods of prevention can be determined.

Although the laboratory and small-scale experiments have shown that the propagation of flame in dust explosions can be prevented by the use of "inert gases" it is necessary to determine definitely if it is commercially practicable to use installations of this nature. This will require further experimental engineering work relating to the securing of inert gases from the boiler flues and the developing of proper equipment for its introduction into grinding machines and milling equipment. This is a very important phase of the work, since a large number of explosions are continually occurring in plants where flammable dusts are produced during grinding operations.

In the construction of industrial plants consideration must be given to dust explosion prevention. The construction should be of such a type that dust cannot collect or settle in certain parts of the plant and thereby increase the explosion hazard.

Development of effective methods for the control or

²CHEM. & MET. ENG., vol. 23, No. 19, p. 915, Nov. 10, 1920.

FIG. 3. BINS WITH "STEEL TROUGH-PLATE CONSTRUCTION" WRECKED BY DUST EXPLOSION

FIG. 4. METHOD OF GROUNDING COTTON GIN

the elimination of static electricity generated by the mechanical equipment in industrial plants is another important question which should be given attention. Satisfactory results have been obtained in the prevention of thresher explosions and fires in the Pacific Northwest and also in the prevention of cotton gin fires in the South assigned to this cause.

The development of aspirating systems for dust removal in grain elevators and similar industries, with specified limitations, and the preparation of a code covering the use of same should receive special consideration. In many industries this is already an essential requisite, especially if the product is commercially valuable.

Experimental work to develop effective methods for control of chokeups in elevator legs is essential. More disastrous dust explosions in grain elevators have been assigned to this particular cause than any other.

The designing of equipment for the prevention of flame propagation following the ignition of dust in grinding machines is commanding attention. The efficiency of revolving dampers, pressure vents and similar devices designed for relieving pressure should be determined.

Electrical sources of dust ignition are presenting themselves and must be given attention. While the electric lamp gives the most satisfactory artificial light, certain practices in use with the equipment have resulted in disastrous dust explosions.

The development and application of methods for measuring the quantities of dust suspended in air in grain-handling plants is one of the important phases demanding attention. Such determination is of importance not only to explosion prevention but to the health of the employees as well.

CHEMICAL RESEARCH PROBLEMS

In addition to the experimental engineering work a number of chemical problems demand attention and consideration. The following more important ones are mentioned:

Determination of the flammability of various dusts, of the various methods and conditions under which dusts can be ignited, of the relation of moisture, ash, volatile content and other factors to the explosibility of dust.

Bureau of Chemistry,
Washington, D. C.

Preparation of Small Pieces for Microscopic Examination

By HENRY S. RAWDON*

DURING the preparation—i.e., the grinding and polishing—of the specimens for microscopic examination the edges are rounded and beveled off somewhat unless care is taken to protect them. In many cases such precaution is absolutely necessary—for example, case-hardened steels, coated metals, the fractured ends of test-bars, etc. Often specimens available are too small for use unless held in some kind of a matrix. For all such cases it is very convenient to coat the specimen with a heavy deposit of electrolytic copper, to mount it in a matrix of some kind and then to cut and polish a section through the resulting duplex specimen.

FIG. 1. VERY FINE COPPER WIRE MOUNTED FOR EXAMINATION. X 1

The common acid sulphate bath consisting of 250 g. crystallized copper sulphate and 50 g. (approximately 30 c.c.) concentrated sulphuric acid and water sufficient to make 1 liter of solution may be used for the solution in which the specimens are copper-plated. For iron, steel, zinc-coated articles and the like it is necessary to plate the specimen with a thin coating first in a nearly neutral bath before using the acid-sulphate bath, otherwise a spongy deposit will result if the specimen is inserted directly into the acid-sulphate bath. This preliminary coating may be very conveniently deposited by means of a cuprous cyanide bath.

Such a solution may be made as follows: The precipitate formed by mixing aqueous solutions of 300 g. each of copper sulphate and sodium carbonate (crystallized) is added to 5 liters of water. This is then reduced to the cuprous condition by adding 1 liter of water containing 200 g. sodium bisulphite. A more convenient way, however, is to bubble sulphur dioxide gas from a cylinder of the liquefied gas through the liquid and the suspended precipitate, until the color indicates that the reduction is complete. One liter of water in which 250 g. crystallized sodium carbonate has been dissolved is added; this is followed by a liter of water containing 250 g. potassium cyanide in solution and the whole, which upon shaking should give a clear solution, is diluted to a volume of 10 liters. In many cases, particularly with copper alloys, it is very desirable to deposit a preliminary layer of nickel before the heavy

FIG. 2. ONE OF THE WIRES OF FIG. 1. X 100
Etched with ammoniacal solution of copper ammonium chloride.

FIG. 3. SMALL STRIP OF COPPER. $\times 100$
Etched with ammoniacal solution of copper
ammonium chloride.

copper layer is added, so that there will be no uncertainty as to the line of demarcation between specimen and coating. This has been found very necessary in such problems as the microscopic study of corrosion of brasses and bronzes. A very convenient solution may be made up as follows: Nickel ammonium sulphate, 90 g.; ammonium chloride, 22.5 g.; boric acid, 15 g. and sufficient water to produce a volume of 1 liter.

After the specimens are heavily plated they are mounted as follows: A short section of brass or other tubing is filed smooth on one end and placed, with this smoothed end down, upon a block of graphite. The specimen is placed inside the tube with the face to be examined down, and then backed up with a matrix. Molten 50:50 lead:tin solder is used a great deal where gentle heating of the specimen is not objectionable. In the case of hardened steels, etc., an alloy of very low melting point—for example Rose's alloy (lead approximately 28 per cent, tin 22 and bismuth 50, melting point

FIG. 4. SMALL LATHE TURNING OF MILD
STEEL. $\times 100$
Etched with picric acid in alcohol.

approximately 95 deg. C.) or Wood's alloy (lead 25 per cent, tin 13, bismuth 50 and cadmium 12, melting point 65 deg. C.)—may be used. A much cheaper substitute that is very suitable for almost all classes of work is made by mixing litharge (PbO) and glycerine in the form of a thick paste. This is poured around the specimen and will set and form a very hard surface which does not interfere with the polishing of the metal. It is sometimes necessary, however, to detach the specimen from such a matrix after polishing, before etching; this is particularly true if alkaline reagents, such as sodium picrate, are used. Often it is very convenient to cut a cavity in the graphite block so that the speci-

men, which is inserted into this hole, will project beyond the face of the solidified matrix which holds it. The projecting portion is then cut off with a fine hack saw and the metal is ground and polished without removing as much of the whole as would have been necessary if the specimen had been mounted flat within the ring.

The figures show some applications of the plating and mounting of metallographic specimens. Fig. 1 shows the polished face of a specimen prepared for microscopic examination. The material to be examined, copper wire 0.015 in. in diameter, was electrolytically plated with nickel and with copper, imbedded in a matrix of molten tin:lead alloy (solder) and a section of the duplex specimen, after cooling, was prepared.

A cross-section of one of the small wires of Fig. 1 is shown in Fig. 2. The white ring is the layer of nickel; outside of this a heavy layer of electrolytic copper was deposited.

A wire similar to that of Fig. 1 was rolled to a strip 0.003 in. in thickness before mounting in the manner described, then photographed in Fig. 3 at 100 diameters.

Fig. 4 shows a small lathe-turning of mild steel electroplated with copper and then mounted.

Diminished Production of Norwegian Paper Industry

The total number of cellulose mills in Norway is twenty-six. There are sixty-three wood-pulp grinding mills and forty-eight paper and cardboard factories. The total number of workmen employed in these mills is about 15,000. The annual production as of 1918 for these factories was as follows: 438,438 tons of cellulose and wood pulp, worth 132,600,000 crowns (\$35,536,800); 116,889 tons of paper and cardboard, worth 86,200,000 crowns (\$23,101,600), reports Consul-General Osborne, of Christiania. Most of the factories in these industries are located in the eastern part of Norway.

The situation at present for the Norwegian paper industry is not as bright. A large number of the mills have been obliged to resort to considerable reductions in output, and some of them have been forced to close, as has been the case with Torp Papirfabrik, with its 400 workmen. There are in the Norwegian paper factories from seventy-five to eighty paper machines, of which at present about one-half are idle. At some of the factories work is carried on only three days a week, and at others for five days a week. At the Borregaard factories, which have a capacity of 23,000 tons of paper a year—i. e., about one-fourth of the production of the entire country—a reduction of 50 per cent has been made. As yet no reduction in production has been made at the Borregaard cellulose mills, which have a capacity of 55,000 tons of cellulose annually.

One of the leading exporters stated recently that the supply of paper on hand in Norway was greater than the demand. There are practically no sales. In Copenhagen, where prices are lower, there are large stocks with no buyers. He further states that the prospects for the future are uncertain and that conditions will not improve until stocks in foreign countries have been consumed.

With regard to the wood-pulp situation, he states that as yet there has been no reduction in production in Norway, with the exception of cases where the production of wood pulp is being carried on in connection with the manufacture of paper. The stocks of cellulose and wood pulp on hand are not as large as those of paper.

Investigations of the Chemical Literature—II

Suggestions for Library Research in Public Documents and the General Periodical Literature in English, German and French—Periodicals Covering Special Fields—Check Lists and Union Lists of Periodicals*

By FRANK E. BARROWS

Public Documents

COPIES of some Government publications are sent free upon request to the particular bureau or department from which they are issued. When they are not thus available copies can be obtained from the Superintendent of Documents at the Government Printing Office, Washington. Price lists of Government publications relating to different subjects are issued by the Superintendent of Documents and are sent free upon request. The following is copied from one of these price lists:

The Government of the United States is the greatest of all publishers of scientific works. It employs thousands of scientists, who are engaged the year round in making researches and investigations in all branches of agriculture, in geology, in mining, in electricity, in chemistry, in astronomy, in engineering, in aviation, in preventive medicine, in forestry, in irrigation, and almost all other branches of scientific inquiry. The arts of war as well as those of peace are also actively cultivated. The greatest art of all, that of free government, is strenuously carried on by President, Cabinet, Senators and Representatives.

The results of all these activities of the most comprehensive and effective organization ever known are constantly reduced to print and poured out in an incessant flood from the largest printing works in the world.

These publications of the Government Printing Office in Washington constitute the Public Documents of the United States.

The greater number of them are sold by the Superintendent of Documents, located in the Government Printing Office. The Government did not establish this sales office for purposes of profit, but as a public convenience. The prices charged cover only paper and printing, no charge being made for the services of the statesmen and scientists who are the authors of the astonishingly varied books, pamphlets, periodicals and maps, and no commissions being allowed to anybody. The documents even have the freedom of the mails and are sent without postage.

The only condition is that payment be made in advance of shipment. The Superintendent of Documents is not authorized to supply free copies, except of his price lists, and it is useless to ask him to do so.

Separate lists of publications of some of the Government departments or bureaus are also published—for example, the Geological Survey publications, those of the Bureau of Mines, those of the Library of Congress, etc., and lists of these are obtainable upon request.

Since 1914 the *Journal of Industrial and Engineering Chemistry* has had abstracts of Government publications.

Periodicals

The periodical literature is so extensive that a comprehensive search through it is often difficult, yet it forms one of the most valuable fields of search because of the numerous original papers which it contains and the wide field which it covers.

Frequently it is possible through the general reference works (previously referred to) to obtain reference

to many of the relevant papers of the periodical literature. In organic chemistry the searcher may thus begin with Beilstein and Richter; in inorganic chemistry with Gmelin-Kraut or Abegg; and from these or other reference works he will be directed to the periodicals where the original papers are to be found. The extent to which the periodical literature can be covered in this way will vary greatly with different subjects.

Where suitable general reference works are not available, or when they have been exhausted, the searcher must turn to the periodicals themselves. The abstract journals are of special value for search purposes, because of the wide field which they include. *Chemical Abstracts* is thus an abstract index or digest of about 783 other periodicals covering the whole field of chemistry and chemical industry.

Cumulative or general indexes covering a number of years are also of particular value. A preliminary examination of a few of these general indexes will often enable the searcher to tell whether the literature of the subject he is investigating is abundant or meager, and in what direction the search can most profitably be continued.

In looking up original articles it will frequently be found that one article contains reference to many others of earlier date relating to the same general subject. These references may represent the results of a comprehensive search which the writer of the article made in preparation for his own investigations. Not infrequently one article will thus give a fairly complete review of the prior available sources of information along the very line in which the searcher is interested. Some of the prior articles thus referred to may in turn refer to others, and so on.

Again, bibliographies will sometimes be found either in the periodicals themselves or in some other publication of which the citation is given, and these bibliographies may give the results of an extended search made by the bibliographer in its preparation.

By making use of short cuts, such as bibliographies or articles giving the results of searches made by others, cumulative indexes of periodicals, abstract journals and general reference works, the searcher will frequently be able to obtain much of the readily available information upon any particular subject within a comparatively short time.

ABSTRACT JOURNALS IN ENGLISH

In making a comprehensive search, however, it is necessary to proceed in a systematic manner through the periodical literature itself. The abstract journals will naturally receive first consideration. The ten-year subject-matter index of *Chemical Abstracts* (1907-16) will furnish one of the best starting points for searching the recent literature. The annual indexes and the current numbers of *Chemical Abstracts* will

*For Part I see CHEM. & MET. ENG., vol. 24, No. 10, p. 423, March 9, 1921.

bring the matter practically up to date. It should be kept in mind, however, that *Chemical Abstracts* was less complete during the early years of publication, and that, complete as it now is, it cannot be relied upon as exhaustive or as including reference to everything of interest appearing in other chemical publications.

Next to *Chemical Abstracts*, the most valuable abstract journals in English are the *Journal* of the Society of Chemical Industry (published since 1882), and the *Abstracts* of the London Chemical Society.

The *Journal* of the Society of Chemical Industry has cumulative indexes for the periods 1882 to 1895, and 1896 to 1905, and annual indexes thereafter. It contains many original works, as well as a large number of abstracts, and it reflects and records the development of chemical industry in Great Britain, and, to a lesser extent, in other countries.

The *Abstract Journal* of the London Chemical Society is less comprehensive in the field it includes than *Chemical Abstracts*, but its abstracts are often more complete. It has been published as a separate publication since 1878. Prior to that date the abstracts appeared as a part of the *Journal* of the society. There are cumulative indexes covering the period from 1841 to 1872, and for each of the ten-year periods thereafter up to 1912.

Chemical News is another English periodical with a useful general index for the first 100 volumes, from 1860 to 1909.

Prior to *Chemical Abstracts* (1907), the abstract section of the *Journal* of the American Chemical Society was known as the *Review of American Chemical Research*. It first appeared in the *Technology Quarterly* for the year 1895, and continued as a part of that publication through 1901.

Beginning with vol. 3 (year 1897), the *Review of American Chemical Research* also appeared as a publication of the American Chemical Society, and continued to do so up to and including vol. 12, of the year 1906. From 1895 to 1901 it was contributed by members of the instructing staff of the Massachusetts Institute of Technology (Arthur A. Noyes, editor). In the first issue of 1895 (*Technology Quarterly*, vol. 8, p. 90) it was stated that:

The purpose of this publication, which is hereafter to appear serially in this journal, is to present in a concise form a review as complete as possible of all original work having a chemical bearing published in the United States after the beginning of the year 1895.

While this publication is not comparable in its scope or value with *Chemical Abstracts*, yet it is of particular interest to American chemists as the predecessor of *Chemical Abstracts* and as a review of American research.

The *Journal* of the American Chemical Society is provided with a general index for the period from 1879 to 1898.

The *American Chemical Journal* also has cumulative indexes for the first ten volumes (1879 to 1888), for vols. 11 to 20 (1889 to 1898) and for vols. 21 to 50 (from 1899 to 1913). In 1914 it was incorporated with the *Journal* of the American Chemical Society.

OTHER PERIODICALS IN ENGLISH

Other important chemical periodicals in English are the following:

Journal of Industrial and Engineering Chemistry, published by the American Chemical Society since 1909.

CHEMICAL & METALLURGICAL ENGINEERING; (*Electrochemical Industry*, vols. 1 and 2, 1902-1904; *Electrochemical and Metallurgical Industry*, vols. 3 to 7, 1905-1909; *Metallurgical & Chemical Engineering*, vols. 8 to 18, 1910-1918; CHEMICAL & METALLURGICAL ENGINEERING, beginning with volume 19, 1918.)

Transactions of the American Electrochemical Society, published since 1902, and with a general index for the first twenty volumes (1902-1911).

Engineering and Mining Journal, published since 1866.

Journal of the Franklin Institute, published since 1826, and with indexes for vols. 1 to 120 (1826-1885), 121 to 140 (1886-1895) and 131 to 160 (1896-1905).

This list is not intended to be complete, and many others could be added, particularly those relating to special fields, such as metallurgy, oils, pharmaceutical chemistry, etc.

"MINERAL INDUSTRY" AND "MINERAL RESOURCES"

In the metallurgical and mineral field, "Mineral Industry" and "Mineral Resources" are deserving of special mention.

"Mineral Industry" has been published since 1892, when its first volume appeared as:

A statistical supplement of the *Engineering and Mining Journal*, the mineral industry, its statistics, technology and trade, in the United States and other countries from the earliest times to the end of 1892.

It contains many articles on metallurgy, and a considerable number of bibliographies.

"Mineral Resources" is published annually by the Geological Survey, and has been published since 1882. In addition to its statistical information and many special articles on mineral production and technology, it also contains a considerable number of bibliographies.

GERMAN CHEMICAL PERIODICALS

If the searcher is limited to the field of English literature, he may nevertheless make an extended search through the various cumulative indexes, abstract journals and other chemical periodicals, such as those above referred to and others relating to special fields. In any comprehensive investigation, however, the searcher will find it a serious handicap if he does not have a working knowledge of French and German, particularly German, since so much of the chemical periodical and technical literature is published in these languages, and especially in German, and since so many of the general reference works and works on special subjects are published in German.

Among the German periodicals *Chemisches Centralblatt* is the abstract journal corresponding to *Chemical Abstracts*. It goes back to 1856, and has general indexes covering at least part of the volumes since that time.

Another valuable German abstract journal is the *Jahresbericht über die Fortschritte der Chemie*. It has been published since 1847 and has cumulative indexes covering about ten-year periods up to 1904.

For industrial chemistry, Wagner's *Jahresbericht der Chemischen Technologie* is a valuable record of chemical technology in German and has cumulative indexes covering about ten-year periods from 1859 to 1904.

The *Berichte der Deutschen Chemischen Gesellschaft*, published since 1868, included abstracts up to 1896. It has general indexes up to 1907.

Other important German chemical periodicals are the

following, although the list is not intended to be complete:

Zeitschrift für Angewandte Chemie, with cumulative index covering the period from 1887 to 1907.

Zeitschrift für Anorganische Chemie, with a general index for the first fifty volumes from 1892 to 1906.

Zeitschrift für Physikalische Chemie, with cumulative indexes covering the first fifty volumes from 1887 to 1905.

Journal für Praktische Chemie, published since 1828, and with cumulative indexes.

Dingler's *Polytechnisches Journal*, published since 1820.

Liebig's *Annalen*, published since 1832 and with general indexes up to 1911.

Poggendorff's or Wiedmann's *Annalen*, published since 1824, with Gilbert's *Annalen* taking it back to 1799.

Die Chemische Industrie, published since 1877.

Monatshefte für Chemie, published since 1880.

FRENCH CHEMICAL LITERATURE

The French literature is less extensive than the German, but there are likewise abstract periodicals and periodicals with general indexes.

The *Bulletin de la Société Chimique de France* (prior to 1907 *Bulletin de la Société Chimique de Paris*) has been published since 1858 and contains abstracts. It also has general indexes up to 1906.

The *Annales de chimie et de physique* goes back to 1789 and for a long time contained abstracts. It has general indexes up to 1903.

The *Comptes rendus* has been published since 1835 and has general indexes up to 1900.

The *Revue générale de chimie pure et appliquée*, published since 1899, with its supplement, the *Répertoire général de chimie pure et appliquée*, published since 1901, is an abstract and review periodical.

The *Revue de chimie industrielle* has been published since 1890.

In the French literature (and the same is true of the literature of other countries) much of the chemical literature is contained in the general science publications—e.g., the *Moniteur Scientifique*, published since 1857.

PERIODICALS COVERING SPECIAL FIELDS

In addition to the periodicals above mentioned, there are many more, including other periodicals of the same countries, as well as periodicals of other countries. In particular there are many periodicals relating to special fields, which those interested in those fields will naturally include in their investigation. We thus find periodicals devoted to rubber, oils, gas, colloids, metallurgy, electrochemistry, physical chemistry, medicinal chemistry, etc. A more detailed discussion of these various fields and periodicals is outside the scope of the present paper. The searcher will readily locate and identify the available periodicals of interest in connection with his investigation from the general reference works, from the abstract journals, or from the card index catalogs.

Not infrequently the searcher will be referred to periodicals which are not accessible in the library in which his search is being made, and it may be important to obtain further information about a particular article in such a periodical, or to find out whether the periodical itself is available in some other library.

If the date of publication and the author are known, a search of the contemporaneous periodical literature may disclose that the same article was reproduced, or that abstracts of it were published, in other periodicals. The same original article may thus be abstracted in *Chemical Abstracts*, in the *Abstracts* of the London Chemical Society, in the *Journal* of the Society of Chemical Industry, in *Chemisches Centralblatt*, and in other abstract or review periodicals, and it may also be reproduced in periodicals of other countries.

To ascertain whether any particular periodical is available in other libraries, reference must be had to the available check lists of these libraries.

CHECK LISTS OF PERIODICALS

For periodicals prior to 1895 the most valuable library check list of periodicals is that of Bolton in his "Catalogue of Scientific and Technical Periodicals, 1665-1895." This list includes 133 American libraries and about 3,160 scientific and technical periodicals, and indicates in which libraries each periodical may be found.

Various other check lists and union lists of periodicals have been issued for certain libraries, or the libraries of certain cities, including the following:

Union List of Periodicals, Transactions, etc., currently received in the Principal Libraries of the District of Columbia, pub. 1901, by the Library of Congress.

Catalogue of Technical Periodicals, Libraries in the City of New York and Vicinity, pub. 1915, by the United Engineering Society.

A List of Serials in the Public Libraries of Chicago and Evanston, pub. 1901, by the Chicago Library Club, and the John Crerar Library Supplement, pub. 1906.

A List of Current Periodicals in the Reading Room, the John Crerar Library, Chicago, pub. 1902.

A List of Serials in the Principal Libraries of Philadelphia and Its Vicinity, pub. 1908, and Supplement, pub. 1910. (Bulletins of the Free Library of Philadelphia, Nos. 8 and 9.)

A List of Periodicals, Newspapers, Transactions and Other Serial Publications Currently Received at the Principal Libraries of Boston and Vicinity, pub. 1897.

A List of Periodical Publications Currently Received by the Public Library of the City of Boston, pub. 1903.

Report of the Committee on "A List of the Scientific and Technical Serials in the Libraries of the State of Indiana." (Reprint from Ind. Acad. of Sci. Report for 1913.)

A Joint Catalogue of the Periodicals, Publications and Transactions of Societies and Other Books Published at Intervals, in the Various Libraries of the City of Toronto, pub. 1913, Univ. Press, Toronto.

Periodicals and Other Serials Currently Received by the Carnegie Library of Pittsburgh, 7th Ed., pub. 1915.

Current Periodicals on File in the Reading Room, Library of the Franklin Institute, Philadelphia, pub. 1916. (Bull. 4.)

Union List of Serials in the Libraries of Rochester, pub. 1917, Rochester Pub. Library.

Legal Notes

BY WELLINGTON GUSTIN

Employee May Recover Damages for Accident That Aggravates a Disease

An employee of the Coffeyville (Kan.) Vitrified Brick & Tile Co. had his foot lacerated while attempting to start a gas engine. Later he was found to be suffering from multiple sclerosis, which, according to the medical testimony, is a hardening of many areas of the brain and spinal cord which have become infected by some organism or poison that causes a deadening of the cells, from which they never recover, for the reason that they have no blood vessels to nourish them. When the nerve center hardens or becomes destroyed it fails to function—that is, to carry along the impulses from the brain.

About two years after the injury a trial was had and the court gave the employee compensation of \$4,513.11. An appeal was made on the ground that the evidence did not establish the fact that the disease was caused by an injury arising out of and in the course of his employment.

There was a conflict in the testimony of physicians for both parties over the question whether multiple sclerosis could develop from a traumatic injury immediately after such injury. The authorities agree that there are various causes that produce the disease, and some include acute infection, or it may come from measles, scarlet fever, smallpox, whooping cough and other infectious diseases. Many include traumatic injuries, but the authorities indicate that in 50 per cent of the cases it was impossible to determine the cause. The physician of the injured employee gave his opinion that the condition of employee was due to an injury or shock which aggravated and may have been the absolute cause of the disease. The Supreme Court of Kansas affirmed the jury's verdict that the injury did precipitate or contribute to the development of the disease and was fully responsible therefor.

"The courts very generally hold that, if an existing disease is aggravated by accident or injury, compensation must be paid for the resulting injury. Note L. R. A. 1917 D., pages 105-129, 130.

"Even where a workman dies from a pre-existing disease, if the disease is aggravated or accelerated under circumstances which can be said to be accidental, his death results from injury by accident. 279 Ill. Rep., 356."

In a Connecticut case it was held that:

"Whatever predisposing physical condition may exist, if the employment is the immediate occasion of the injury, it arises out of the employment because it develops within it." 90 Conn., 539.

It has been held sufficient to justify an award under the workmen's compensation act in Maine, where "by weakening resistance or otherwise, an accident so influences the progress of an existing disease as to cause death or disability."

In a Massachusetts case, a workman "with an already impaired heart suffered further injury through the muscular exertion" required by her work, and it was held that she could recover compensation

not only for that part of the injury resulting directly from the work, but for that following directly from the previous defective condition of her heart.

The Kansas court said: "It is true that under our compensation law a workman may not recover compensation for an incapacity resulting merely from a disease, although the disease developed in and was caused by the nature and condition of his employment. It is only where he has sustained some accidental injury, arising out of and in the course of his employment, which aggravates a disease and thereby causes incapacity, that he may recover compensation."

Liability of Buyer by Acceptance of Part of Shipment

The liability of a buyer by an acceptance of part of the goods shipped him was a question presented the Court of Appeals of Kentucky in the case of B. R. C. Battle Co. vs. Peaslee-Gaulbert Co. The latter, a wholesale company, of Louisville, Ky., ordered a bill of glass bottles of the former, a manufacturer of Louisiana. While seven different kinds of bottles were ordered, but four kinds were shipped, and not in the quantities ordered except in one instance. Two kinds of the bottles were defective and the buyer declined to pay for them. The seller ordered a return of the whole shipment within a few days after receiving the complaint of the buyer.

Subsequently the seller filed suit to cover for the entire shipment, amounting to \$1,609.76. The buyer admitted liability in the sum of \$723.20 for the good bottles, and resisted payment for the defective bottles by counterclaim for damages of an alleged warranty. Upon trial of the case the seller recovered a judgment against the buyer for \$259.52.

The trial court held that the contract was severable, and permitted the buyer to recover, upon its counterclaim, damages for breach of an implied warranty as to the two rejected kinds of bottles, of which action alone complaint is made upon the appeal. The seller contended that the contract was entire, and not severable, and that by the acceptance of a part of the shipment the buyer became liable for the whole shipment.

On appeal the Court of Appeals said the several different kinds of bottles involved were separately priced and separately invoiced, and constituted different items not inherently interdependent, but easily severable, of a single order in which the aggregate sum does not seem to have been considered or mentioned. Such contracts, says the court, may be either severable or entire, depending upon their terms and the intention of the parties involved, to be ascertained from the language employed, the character of merchandise, attendant circumstances, and the act of the parties. (2 A. L. R., 643.) Further it appears, as the court found, that the seller did not itself regard the contract as entire, because without agreement so to do, it accepted and complied with only several parts thereof. And there was nothing in the contract nor in the acts of the parties to indicate that either considered it other than a severable contract, except the telegram and letters of the seller to the buyer after it had been informed by the buyer that the latter treated and considered the contract as severable, by accepting in part and rejecting in part the goods shipped. In like manner the court pointed out that the seller had treated it as severable, by accepting in part and rejecting in part the order tendered it by the buyer.

Influence of Silicon Upon the Properties of Ferrosilicon

Pure Commercial Alloys Containing More Than 50 per Cent Silicon Contain the Primary Compound FeSi and a Decomposition Product FeSi_2 —Very Accurate Estimates of Silicon Content Can Be Made Quickly by Specific Gravity Determinations

By A. T. LOWZOW

TRANSLATED* BY O. A. HOUGEN

Research Chemist, Carborundum Co., Niagara Falls, N. Y.

FERROSILICON has repeatedly been studied by different investigators. These investigations have been based chiefly upon ferrosilicon produced in small charges, the alloys being then treated with different solvents and the residues analyzed. Hahn assigned¹ the compounds Fe_2Si , FeSi and FeSi_2 . De Chalmot² described the compound Fe_3Si_2 . His determinations, however, checked up so poorly that they were not accepted as full proof of the existence of this compound, and none of the later investigators have encountered it. Gins³ believed that the compound Fe_3Si was produced in the blast furnace from 10 per cent ferrosilicon. Tick maintained that this compound did not exist in the pure state, but only in combination with manganese such as the compound $(\text{FeMn})_3\text{Si}$. Naske⁴ believed that he had found the compound FeSi_3 in 50 per cent ferrosilicon after treatment of this alloy with hydrofluoric acid. This compound was not encountered by any later investigators and there is little proof of its existence.

In 1905, W. Guertler and G. Tammann⁵ published the results of their researches on ferrosilicon, based chiefly

in Fig. 1, they encountered the two compounds Fe_2Si and FeSi , but not the compounds Fe_3Si , Fe_3Si_2 , FeSi_2 and FeSi_3 . However, we are not justified in excluding the existence of these last-named compounds on this account. Guertler and Tammann worked with very small charges at an average rate of heating and cooling of 100 deg. per minute. It is easily understood that the manner of crystallization obtained in this way is different from the manner obtained in large commercial charges; for instance, Dr. Pick (1906) found crystals of FeSi_2 in large blocks of ferrosilicon which had cooled slowly. On the whole, the following list represents the supposed ferrosilicon compounds, all but the first being relatively definitely proved:

	Per Cent Si		Per Cent Si
Fe_3Si	14.289	FeSi	33.33
Fe_2Si	20.00	FeSi_2	50.00
Fe_3Si_2	25.00	FeSi_3	60.00

MATERIALS FOR THE PRESENT INVESTIGATION

For investigation a series of samples of ferrosilicon containing from 49.1 per cent Si to 77.46 per cent Si were obtained from Borregaard, and a sample containing 93.41 per cent Si from Kopperaaen, Meraker.

The following samples were selected and analyzed:

No.	Per Cent Si		Per Cent Si
1.....	93.41	12.....	66.25
2.....	77.50	13.....	65.70
3.....	76.28	14.....	64.10
4.....	76.00	15.....	61.95
5.....	75.90	16.....	61.40
6.....	74.82	17.....	59.10
7.....	72.90	18.....	56.01
8.....	72.55	19.....	52.30
9.....	72.00	20.....	50.90
10.....	71.25	21.....	49.10
11.....	70.32		

FIG. 1. EQUILIBRIUM DIAGRAM FOR IRON-SILICON ACCORDING TO GUERTLER AND TAMMANN (1905)

upon thermal investigations. They melted Fe (99.77 per cent) and Si (98 per cent Si, 1 per cent Fe) in a porcelain test-tube placed in an electric furnace and observed the cooling and heating curves. Thermoelements were protected by ordinary porcelain tubes in the investigation of alloys containing less than 75 per cent Si. With higher silicon content the porcelain tubes were protected by sheet platinum and magnesia. Melting was performed in an atmosphere of nitrogen. In their investigations, results of which are diagrammed

It was necessary to polish the specimens with the greatest care, because there was a tendency for large pieces to break loose from the surface, especially with alloys between 55 and 70 per cent Si. Alloy No. 18 with 56.01 per cent Si was so brittle that it could easily be broken apart with the fingers. The most brittle specimens were bonded with Canada balsam in a bunsen flame whereby they received sufficient mechanical strength for polishing.

Eutectic and separated crystalline aggregates could easily be distinguished under the microscope without etching. An attempt was made to etch the sections with weak hydrofluoric acid and weak NaOH solutions in order to see the structure of the crystalline aggregates. However, this etching gave unfavorable results, the portion of the sections which were broken out became larger and the image in the microscope less distinct. Crystals of FeSi_2 etched satisfactorily.

FIGS. 2 TO 5. MICROSTRUCTURE OF FERROSILICON SAMPLES
 Fig. 2. 93.4 per cent Si. $\times 50$. Fig. 3. 77.5 per cent Si. $\times 50$. Fig. 4. 56 per cent Si. $\times 65$. Fig. 5. 49.1 per cent Si. $\times 20$.

In silicon-rich melts, according to the diagram (Fig. 1), one would expect to find silicon crystals in a surrounding eutectic having a composition of about 60 per cent Si and 40 per cent Fe. This proved to be the case, except that the eutectic apparently has a composition of about 55 per cent Si and 45 per cent Fe. Crystals of silicon were observed as rather long crystalline aggregates in the midst of the surrounding eutectic; they are gray and have a bright hard surface with only a few small pieces chipped away from the surface. The surrounding eutectic presents a dotted structure with a light gold color. Large portions of the eutectic which were removed during polishing appear as black spots under the microscope.

Silicon in alloy No. 1 (93.41 per cent Si) appears in large smooth surfaces, separated by veins of eutectic (Fig. 2). The relative proportion of Si and eutectic could not be determined with accuracy by the planimetric method on account of the relatively large sizes of the crystals.

In Fig. 3 I have found it possible to obtain more truly representative portions of silicon and eutectic in one microsection. An alloy containing 56.01 per cent Si shown in Fig. 4 is the lowest in the series where crystals of pure silicon are found. This is not a representative picture of the distribution of Si, but it is that part of the section which shows the maximum amount of crystallized silicon; other portions were entirely without crystallized silicon. Intermediate analyses (alloys 2 to 17) show a progressively diminishing silicon content and an increasing eutectic content. As above noted, the eutectic works out to be about 55 per cent Si, 45 per cent Fe.

Besides the sections which are illustrated above, alloys 13, 14, 15 and 16, with 65.70, 64.10, 61.95 and 61.40 per cent Si respectively, were also investigated with the microscope. These samples, together with No. 17, approach the percentage corresponding closely to the compound FeSi, proposed by Naske. I could, however, find no indication of such a compound. All specimens showed

a uniform decrease in Si and increase in eutectic content. In alloy 6, containing 74.82 per cent Si, I estimated that the amounts of crystallized silicon and eutectic present were almost equal. Figuring eutectic to contain 55 per cent Si, we obtain:

	Per Cent Si
50 per cent Si.....	50
50 per cent eutectic.....	27.5
Total.....	77.5

a departure of about 3 per cent from the correct amount as given by chemical analysis.

Alloy 19, containing 52.3 per cent Si, shows the same eutectic mixed with a new crystal form, FeSi. (See Fig. 1). Measurement of various photographs of this alloy show that the crystallized FeSi comprises from 10 to 15 per cent of the whole surface. In the former case:

	Per Cent Si
90 per cent eutectic.....	49.5
10 per cent FeSi.....	3.33
Total.....	52.83

In the other extreme, 15 per cent FeSi:

	Per Cent Si
85 per cent eutectic.....	46.75
15 per cent FeSi.....	5.00
Total.....	51.75

Whether one decides 10 or 15 per cent FeSi makes only about 1 per cent difference in the resultant total silicon (compare with 52.3 by chemical analysis). FeSi has a strong metallic luster and a white color. Fig. 5 is a photomicrograph of alloy 21. This alloy is estimated to contain about 34 per cent FeSi.

	Per Cent Si
66 per cent eutectic.....	36.3
34 per cent FeSi.....	11.3
Total.....	47.6

an error of about 1.5 per cent.

In ferrosilicon with silicon content ranging from 48 to 60 per cent a large number of small geodes are found. Fig. 6 shows the largest one found. In occasional pieces a whole series of small geodes were found varying from 0.5 to 1.0 mm. in diameter.

In order to investigate the contents, individual crystals were picked out carefully, avoiding as far as possible taking portions which lay directly upon the solid ferrosilicon alloy, in order not to risk contamination. The fragments gave the following analysis:

	Per Cent Fe	Per Cent Si
1.....	51.0	50.8
2.....	49.3	49.1

This corresponds closely to the compound FeSi.

FIG. 6. LARGEST GEODE FOUND. $\times 2$.

The first matter which had to be determined was whether geode contents consisted of an actual compound, or if it were only an ordinary alloy which had assumed this form. A small blade from a geode, after etching with hydrofluoric acid, and magnified 100 times, showed individual crystals lying closely together, a homogeneous crystalline formation with no

FIG. 7. LARGE GEODE IN 75 PER CENT FERRO-SILICON. NATURAL SIZE

foreign ingredients present. It is, therefore, well established that these geode contents consist of one kind of crystal, which according to the above analyses must be the compound FeSi_2 .
Fig. 7 shows a crystalline geode found in ferrosilicon about 75 per cent Si. Its analysis gave:

	Per Cent Si	Per Cent Fe
1.....	82.04	17.48
2.....	80.95	18.80

If the geodes consisted of homogeneous crystals it would correspond approximately to the compound FeSi_2 .
Microscopic examination showed at once a compound structure. After observing the section in the microscope it is seen that the geode consists of two distinct constituents—six cornered crystals, lying one on top of the other with an intermingling eutectic; the same eutectic, light gold in color, which was noticed in previous work (55 per cent Si). The maximum eutectic comprised 10 per cent of the whole. For example, suppose 10 per cent eutectic present. Then, if the crystals were to consist of pure silicon we could obtain:

	Per Cent Si
10 per cent of eutectic contains....	5.5
90 per cent assured pure.....	90.0
Total.....	95.5

Since the analysis gave only an average of 81.5 per cent Si, this hypothesis is excluded.
Assuming that in the average analysis (81.5 per cent Si and 18.5 per cent Fe) all the iron exists as a portion of the eutectic, the distribution of silicon is:

	Per Cent Fe	Per Cent Si
41.1 per cent eutectic contains.....	18.5	22.6
The chemical analysis is.....	18.5	81.5
Balance of pure silicon.....		58.9

The probability is, therefore, that the geode is more nearly constituted as follows:

	Per Cent
Free silicon.....	58.9
Unresolved eutectic.....	31.1
Eutectic surrounding the crystals.....	10.0
Total.....	100.0

Particles about 5 mm. diameter of alloys 1, 4 and 11

were treated with cold 20 per cent NaOH solution. After a lapse of one day the particles crumbled into small bits, and after a lapse of one week no more dissolved.
The weakly magnetic undissolved residue was filtered off, washed, dried, and analyzed, giving:

Sample	1	4	11
	Per Cent Si	Per Cent Si	Per Cent Si
1	54.66	54.90	55.30
2	54.45	55.20	55.25
	Per Cent Fe	Per Cent Fe	Per Cent Fe
1	45.45	45.66	44.80
2	45.30	44.97	44.80

This gives an average of 54.96 per cent Si, 45.13 per cent Fe. The caustic has, therefore, dissolved out the crystallized silicon from the alloy and left remaining an alloy which shows the same constant composition for all three samples. This is the eutectic which is not attacked by the cold caustic. According to this, the composition of the eutectic should be 55 Si, 45 Fe.
In the diagram (Fig. 1) the position of this eutectic is shown at about 60 per cent Si (atomic percentage = 75). The few investigations which they carried out upon this eutectic and the large sources of error which are attached to their work indicate that the position of the eutectic at 60 per cent Si must be wrong. The eutectic must surely not be far from 55 per cent Si and 45 per cent Fe. The curves, therefore, obtain a slightly altered appearance as shown in Fig. 8.

FIG. 8. EQUILIBRIUM DIAGRAM FOR IRON: SILICON ACCORDING TO LOWZOW AND HOUGEN (1919).*

The line ef becomes steeper in slope than the line fg ; also for two alloys lying equidistant from the eutectic and on opposite sides when computed in atomic percentages show a great difference in the relative proportions of eutectic with their respective Si and FeSi .
The undissolved residues from alloys 4 and 11 after one week of treatment with cold caustic were treated with warm 20 per cent NaOH for one week. The warm caustic attacks the small eutectic grains, which then fall into a powder. The powder, washed and dried, possesses greater magnetic properties than the previously discovered eutectic. The analysis gave:

	Per Cent Si	Per Cent Fe
No. 4.....	33.8	66.3
No. 11.....	33.9	65.9

This corresponds to FeSi —33.4 Si and 66.6 Fe.
The warm caustic dissolved the silicon from the eutectic and left the FeSi undissolved.

*TRANSLATOR'S NOTE: The work of T. Lowzow has established the exact composition of the eutectic FeSi and Si and has explained the formation of the compound FeSi_2 from this eutectic upon slow cooling. From interpretation of the modified equilibrium diagram the translator has drawn up this constitutional diagram. The dotted line below the solidus line merely indicates the probable manner of formation of the compound FeSi_2 and is not intended to even approximate the exact equilibrium conditions.

The specific weights of ferrosilicons given in Höngschmid's works of 1914, "Carbides and Silicides," are:

Fe ₂ Si (20% Si).....	7.0 (after Moissan) 22°C.
	6.75 (after Lebeau) 22°C.
Fe ₃ Si (25% Si).....	6.36 (after De Chalmot)
FeSi (33.33% Si).....	6.17
FeSi (50.00% Si).....	5.40 (after Lebeau)

De Chalmot gives for technical ferrosilicon the following specific gravities:

	12 per Cent Si	25 per Cent Si	46 per Cent Si
Specific gravity..	6.8	6.36	4.85

To determine specific gravity carbon tetrachloride is used; this does not attack any of the constituents of ferrosilicon. One disadvantage of carbon tetrachloride is its large temperature coefficient of expansion and high vapor tension. The specific gravity of carbon tetrachloride was determined in a Spengels pycnometer at 14.9, 17.1 and 20.1 deg. C. respectively, with parallel investigations of distilled water. Results:

Sp.gr. at 14.9 deg. C.....	1.6034
Sp.gr. at 17.7 deg. C.....	1.5982
Sp.gr. at 20.1 deg. C.....	1.5936

Ferrosilicon is permeated through its whole mass with gas and air spaces. The specific weight must, therefore, be determined in powder form. To determine this a bottle pycnometer was used. It was found absolutely necessary to work in a thermostat. A couple of investigations were made without the thermostat, with reading of the variable temperatures and corrections to the corresponding specific gravity of carbon tetrachloride; this gave very bad results because of cumulative errors. Temperature of the room was held at about 18 deg., maximum 19 deg., and the thermostat was kept constant at 20 deg. C. After filling the pycnometer with CCl₄ and fitting on the cork it was placed in the thermostat. When the pycnometer had been heated to 20 deg. the contents expanded and the overflow was driven out of the pycnometer through the capillary stem. At the moment when no more CCl₄ came out a cap was placed over the capillary and the pycnometer was dried and weighed. During the first investigations a small glass cap was used, but this did not prevent the CCl₄ from evaporating. By fitting on a small piece of rubber tubing, which was closed at one end by a small glass bulb, all evaporation of CCl₄ was prevented.

After this the weighed amount of ferrosilicon was placed into the pycnometer, filled one-third full with

TABLE I. SPECIFIC GRAVITY OF POWDERED FERROSILICON

No.	Per Cent Si	Sp.Gr.	No.	Per Cent Si	Sp.Gr.
1	93.41	2.542	12	66.25	3.453
2	77.50	2.944	13	65.70	3.560
3	76.28	3.010	14	64.10	3.602
4	76.00	3.050	15	61.95	3.780
5	75.90	3.051	16	61.40	3.857
6	74.82	3.060	17	59.70	4.102
7	72.90	3.162	18	56.01	4.260
8	72.55	3.205	19	52.30	4.200
9	72.00	3.220	20	50.90	4.342
10	71.25	3.222	21	49.10	4.630
11	70.32	3.260			

CCl₄ and shaken well in order to drive out most of the entrapped air. The remaining air was expelled by evacuation. The pycnometer was then filled with CCl₄, stoppered and set into the thermostat. The operation was continued as described above. Results are given in Table I.

These specific gravities are shown graphically in Fig. 9. The points marked 1', 2' and 3' indicate the specific

gravities of FeSi, FeSi₂ and Si respectively. Specific gravities are seen to lie fairly regular between 70 and 78 per cent Si. This is to be expected, because these alloys are produced from iron scrap and quartz and contain a very small amount of foreign constituents. No. 4 lies farthest from the curve; its analysis shows 76 per cent Si, but this determination figured from the specific weight curve should be nearer 75.2 per cent Si.

In the production of high ferrosilicon of about 75 per cent Si, very close estimations of the silicon analysis can be made in less than one hour by this specific gravity method, whereas an ordinary chemical analysis takes almost two days. This has a great commercial significance. By one step an approximate analysis can be rapidly made. If compelled to wait two days for an exact analysis there would be a risk of having the operation of the smelting furnace go wrong before being aware of it.

Poorer conditions exist with lower percentages of Si. The dotted portion of the curve represents the mean of the specific gravities. A variation from this line is to be expected since my ferrosilicon alloys were made from iron ore and quartz, naturally giving a larger opportunity for the introduction of impurities.

In order to determine if the constituent minerals would have this effect upon the specific gravities, thin sections were made upon the following samples:

Number	1	2	11	16	18	20
Per cent Si...	93.41	77.50	70.32	61.40	56.01	49.10

These were inspected in the microscope, using transmitted polarized light. In 1, 2 and 11 no minerals were found. On the other hand 16, 18 and 21 contained fairly small mineral grains in various amounts. One would expect that these were unreduced quartz; however, quartz could not be detected. Ca-Mg silicates were found, which accordingly reduce the specific gravity.

FIG. 9. SPECIFIC GRAVITIES OF POWDERED FERROSILICON

Continuing further with decreasing silicon percentages toward the eutectic (55 per cent Si), the alloy becomes continually duller in appearance. It also becomes more and more friable. No. 18 (56.01 per cent Si) is so friable that it can easily be crumbled with the fingers. Below 55 per cent Si, the alloy changes rapidly in character. Large laminated crystals of FeSi are present and impart to the alloy 50.90 per cent Si a strong metallic luster, a silver white color and great mechanical strength. Alloys which lie a few per cent to the left and up to 10 per cent to the right of the eutectic (55 per cent Si), say between 53 and 65 per cent Si, have, however, fairly little mechanical strength.

United States Export Trade in Corn Sirup
and Corn Sugar

With corn the greatest crop in the United States and a 1920 record yield of 3,199,126,000 bu. of the average farm value of 87.3c. per bu., according to the Bureau of Crop Estimates, it is of current interest to note the magnitude of the export movement in two of its many byproducts—glucose (corn sirup) and grape sugar (corn sugar).

All records were broken in the calendar year 1919 by an aggregate exportation of 255,617,709 lb. of corn sirup and corn sugar, valued at \$15,139,944, or an increase of 346 per cent in quantity and of 338 per cent in value over the 1918 shipments of 57,332,150 lb., invoiced at \$3,458,927. Little variation is shown in the average annual export price of about 6c. per lb. from 1918 to 1919. The United Kingdom ranked first as a market for these products, taking 39,345,968 lb., worth \$2,368,015, in 1918, and 159,033,298 lb., at \$9,563,339, in 1919.

From 1918 to 1919, shipments to France increased from 3,984,452 to 52,042,071 lb.; to Argentina, from 1,793,900 to 6,341,204 lb.; and to Italy from 845,537 to 5,909,980 lb. Considerable gains are also recorded in the 1919 trade with Belgium, Greece, Canada, New Zealand, the Philippines, British South Africa and other countries.

INDUSTRIES UTILIZING CORN SIRUP AND SUGAR

Corn sirup is a distinctively American product. Though less sweet than cane sugar, it can be used in many ways as a satisfactory substitute therefor. Glucose was discovered about 1800. In this country it is largely used in confectionery and in leather manufacture, in the form of an almost transparent, sirup liquid composed of dextroglucose, maltose, dextrine and water prepared from cornstarch by heating with dilute acids. It was formerly used to a large extent in brewing. For converting starch into glucose (hydrolysis), sulphuric acid is generally used. Various forms in commercial demand are "mixing glucose," used by sirup and molasses manipulators; "jelly glucose," for making jellies from evaporated apple juice or other materials; "confectioners' glucose;" "brewers' glucose," used as a substitute for malt in brewing; and "anhydrous grape sugar."

Well-made glucoses are perfectly wholesome and have a definite food value. It is said that the chief objection to their use in food preparations is due to the fact that the consumer is often misled in regard to the value of the products containing them, as glucoses are often used in the manufacture of inferior or adulterated goods. The manufacture in the United States of corn sirups for table use is highly developed, and there is an increasing domestic demand for various popular brands of uniform good quality. This demand may be partly due to the proportionately greater increase in the price of cane and maple sugar and sirups since 1917. Normally, in pre-war times, the value of cane and maple products greatly exceeded those of corn sugar and sirup, but the relative increase in price of the corn products has been very much less. Cane sugar has sold in this country as high as six times its pre-war value, while the price of glucose is only about three times greater. This is apparent in the exports of glucose amounting to 124,140,171 lb., valued at \$2,657,034, in the calendar year 1910, as compared with practically the same quantity,

Years	Glucose		Grape sugar	
	Pounds	Value	Pounds	Value
1910	124,140,171	\$2,657,034	46,791,855	\$937,391
1911	146,643,655	2,953,120	45,249,422	878,841
1912	134,842,547	3,256,550	40,328,283	906,385
1913	165,554,073	3,760,203	40,641,718	906,881
1914	127,201,099	2,895,189	35,681,124	775,036
1915	151,487,376	4,107,547	36,842,686	945,235
1916	136,379,198	3,295,823	38,684,528	993,478
1917	152,076,927	7,158,670	25,765,875	961,908
1918	42,740,417	2,552,637	14,591,733	906,296
1919	220,380,761	13,169,051	35,236,948	1,970,893
1920	124,202,985	7,806,101	9,918,320	618,897

* Nine months ended with September.

124,202,985 lb., exported in the first nine months of 1920, invoiced at \$7,806,101.

VARIATIONS IN EXPORT TRADE DURING LAST DECADE

It will be noted from the accompanying table that while the export trade in glucose (corn sirup) has been greatly extended during the last decade, 1910 to 1920, that in grape sugar (corn sugar) declined in quantity from 46,791,855 lb. in 1910 to 35,236,948 lb. in 1919, but increased in value from \$937,391 to \$1,970,893 in the same time. A still further decline in the exports of grape sugar occurred during the first nine months of 1920—9,918,320 lb., valued at \$618,897, as compared with 24,590,745 lb. invoiced at \$1,321,119 in the corresponding period of 1919.

The combined exports of glucose and grape sugar for the nine months ended September, 1920, are 134,121,305 lb., valued at \$8,424,998, or an average export price for this period of 6.3c. per lb. Corresponding exports in 1919 were 194,681,907 lb., invoiced at \$11,082,078, or 5.7c. per lb.

Tin Plate Industry and Trade in Swansea

The tin plate industry of Great Britain is confined exclusively to South Wales, with the exception of a single plant in North Wales. Of the 82 works in the Welsh tin plate industry, 65 are located within a radius of 18 miles from Swansea. That city may rightly claim, therefore, to be the center of the industry.

The following table from the report of the Royal Metal Exchange of Swansea shows the volume of the trade of the United Kingdom in tin plate, black plate and galvanized sheets for the years 1913, 1918 and 1919, and is applicable to the district of Swansea, since virtually all the tin plate and black plate, as well as the larger part of the galvanized sheets, are produced there.

	1913	1918	1919
	Tons	Tons	Tons
Exports of tin plate	494,497	223,509	289,761
Exports of black plate	71,775	4,571	32,511
Estimated home consumption of tin and black plates	255,798	226,355	229,711
Estimated output of tin black plates	822,070	454,485	551,983
Exports of galvanized sheets	762,075	8,835	186,101

Though the Welsh tin plate industry has a very important home market, the permanent success and further expansion of the industry must depend upon its export trade. Of the home trade which it had in tin plate and black plate in 1913, it recovered 229,711 tons in 1919. Of the export trade in these articles in 1913, it has recovered in tin plate 289,761 tons out of 494,497 tons; and in black plate, 32,511 tons out of 71,775 tons. That is, it has recovered 58 per cent of its pre-war tin plate export trade and 45 per cent of its pre-war black plate export trade.

Whether it will be able to recover a further appreciable per cent of its lost trade is somewhat questionable.

Porcelain Enameling Furnaces

BY C. G. ARMSTRONG*

THE art of ceramics had its beginning when primitive man took such clay as he found at hand and molded it into such shapes as fancy or needs dictated. Sun drying and accidental firing disclosed the secrets of pottery to him and the art of pottery, the forefather of enameling, had its beginning. To claim that the ceramic art was originated by any one race has been proved to be fallacious in view of the incontestable evidence that pottery was made by the Indians of Mexico and the prehistoric people of Egypt and China long before they were aware that any people lived in the world other than themselves.

Archæologists have found ruins along the Nile over 10,000 years old in which pottery played a part, but it is not until 1300 B.C. that we find any trace of glazes or enamels being applied to the pottery. The discovery of glass by the Assyrians, prior to 1300 B.C., is considered to be the beginning of the art of enameling, and the temple of Rameses III contained wonderful examples of enameling which have not been surpassed in magnificence to this day. Thus it is safe to state that enameling had its birth in Egypt.

From Egypt the art of enameling spread to Rome and was carried by the Romans to England, France and Germany at the time of their invasions of those territories.

During the early part of the eighteenth century the art of making miniature enamel pieces on gold, silver and copper assumed fair proportions, and yet we do not find any record of attempts to enamel iron or steel prior to 1840, when a method for the enameling of cast iron by the dry process was discovered. The enamel was applied only on the inside of the receptacle at first, as muffle firing was very imperfect. The muffles of that period were made of cast iron with steel base plates and were far from being satisfactory, though some very excellent pieces of work were turned out.

In 1860 the enameling of sheet iron was begun, and upon the advent of the drawing press and clay muffle in 1870 the process of porcelain enameling steel as we know it today developed into the enameling industry.

FORMULAS

The formulas used in 1850 and those of today, while fundamentally the same, have had to undergo many changes in order to produce an enamel which would have the proper physical and chemical properties to work on the modern basic sheet steels.

In this paper we shall carefully avoid the discussion of formulas, for with the forty or more variable ingredients going into a formula, eight of which on an average are used, there are possibly 76,920,000 formulas. Time is too short even to begin such discussion; furthermore, we have to deal with enameling furnaces—furnaces in which all correct formulas should work properly.

With the development of the industry in Europe and the establishment of an American enameling plant at Woodhaven, N. Y., in 1863, we arrive near home and are prepared to discuss the furnaces.

In the strictly ceramic lines of the porcelain enamel industry having to do with the preparation and applications of the enamel, progress until recently has been

fairly slow and has lagged considerably behind the development of the machinery used in forming the steel shapes for enameling. The designs of furnaces for the firing of the enamel have also been changing very slowly since the inception of the clay muffle in 1870 and until recently there has been no marked improvement. To review the development in porcelain enameling furnaces from the time when they were only a flat hot stone through the different stages of the intermittent beehive oven, cast-iron muffles, clay muffles to the modern muffles would consume too much space. Suffice it to say that since the introduction of the clay muffle no radical changes have been made, except in the placement of the flues and method of firing, until the introduction of the carborundum muffle.

TYPES OF FURNACES

Present-day furnaces may be divided into two classes as to muffle types—the semi-muffle and full muffle—and also several classes as to method of firing, or briefly, coal-fired, producer-fired, semi-producer, recuperative, oil-fired and gas-fired. The electric furnace has not entered the commercial field as yet, due to great heat losses entailed.

Various types of furnaces are used, most of the variations being in the flue system. Very elaborate flue layouts have been constructed in some furnaces with the idea of extracting as much of the available heat as possible from the gases before they leave the furnace. This, of course, is not necessarily always successful, for those flues placed in the roof and upper walls which receive their heat by radiation often are a means of extracting heat from the furnaces and causing the flue gases to leave the furnace at a much higher temperature than they would if taken out by means of shorter flues. The logical thing to do, therefore, is to use a recuperator instead of long flues, or better still use a thin or high-conductivity muffle which will keep the temperature gradient between the flues and the interior of the muffle as small as possible. This feature is conducive to economy, both as to muffle and fuel, since a lower temperature is necessary in the combustion chamber and flues in order to attain and maintain the proper enameling temperature within the muffle. There are furnaces in modern plants where the floors of the muffles are 8 to 12 in. thick with muffle walls 3 in. thick in which a temperature of 3,000 deg. F. (1,649 deg. C.) has to be maintained within the combustion chamber in order to maintain 1,600 deg. F. (871 deg. C.) in the muffle. Such a large temperature difference between the combustion chamber and muffle is not uncommon today and needless to say is not economical. A temperature difference of more than 400 deg. F. (204 deg. C.) between the flue temperature and muffle temperature is not justifiable in the light of the latest developments in porcelain enameling ovens.

FURNACE CONSTRUCTION

In taking up the construction of furnaces for firing porcelain enamel let us first discuss the simplest form, the gas furnace. As is well known, the atmosphere within a porcelain firing furnace must be oxidizing—that is, must have an excess of oxygen present and little or no reducing gases such as carbon monoxide—in order that a smooth product may be obtained. Control of the atmosphere within a gas-fired furnace is easily accomplished and for that reason semi-muffles are frequently used in these furnaces. A semi-muffle is only that part

*Chemical Engineer, Chicago Flexible Shaft Co. Paper presented before Chicago Section, American Ceramic Society, Nov. 27, 1920.

of the muffle which goes to make up the bottom and sides—that is, without a top. Such furnaces are highly efficient as to fuel consumption and are as satisfactory as the full muffle when the operation is understood. A gas-fired furnace is less expensive than any other type, due to its less bulky construction.

Oil-, coal- and producer-gas fired furnaces all fall into one general class whether recuperative or not. These furnaces all require relatively large combustion chambers and full muffle construction.

The general plan upon which all of this type are constructed is to build the combustion chamber or firebox under the rear of the furnace and erect a thick furnace floor over one long central combustion chamber, from the sides of which lateral flues lead to the flues in the wall of the furnace surrounding the muffle. This construction is surrounded by walls of refractory brick backed by several layers of red brick facing in order to conserve the heat. In such furnaces, which are exceedingly common, the temperature difference between the flue gases and the interior of the muffle is generally 800 deg. F. (427 deg. C.) or more, and to see flames emitting from the top of a 15-ft. stack attached to such furnaces is not uncommon. The heavy construction necessitated by the inherent weakness of the fireclay refractories at the temperature of an enameling furnace together with the poor thermal conductivity of these refractories results in a fuel consumption out of all proportion to the small percentage utilized in the burning of the ware. Any development in furnace design which will show a saving of several per cent in fuel will be a boon to the enameler, because his costs of production are gradually approaching his selling prices.

LATEST DEVELOPMENTS IN ENAMELING FURNACES

Before entering into a discussion relative to the latest developments in enameling furnaces it may be better to outline the points of weakness in the old types. For brevity we will itemize their shortcomings:

1. The weakness of the fireclay refractories at the temperature of enameling ovens necessitates the use of exceedingly heavy refractories with such mass as to require days to heat up, and definite control of the temperature of the furnace is impossible.

2. The poor conductivity of the heavy refractory muffles makes it imperative to maintain a flue temperature 800 to 1,000 deg. F. (427 to 538 deg. C.) in excess

SEMI-MUFFLE, GAS FIRED

FULL MUFFLE, GAS FIRED

of the muffle temperature, resulting in high fuel consumption and short life of the refractories.

3. Great mass and poor conductivity of refractories. From three to five days is required to bring a furnace up to heat.

4. Uniformity of temperatures—i.e., plus or minus 10 deg. F. (—12 deg. C.) within the muffles of the old type furnace are almost unknown, and loading to the door can never be practiced.

5. High flue temperatures necessitate bulky construction in order to conserve the heat.

6. Economy of operation of old type furnaces cannot be practiced except at expense of output.

7. The durability or life of the old type muffle furnace is fairly short. Constant repairs and renewals are required and overheating results in its ruin.

8. Shutdowns over Saturday afternoon and Sunday are not practicable.

Now, having listed the shortcomings of the old type furnace, let us see how these are overcome in the new furnaces, point for point:

1. The carborundum refractories used in the newer furnaces, having a mechanical strength approximately ten times that of ordinary fireclay when cold and retaining this strength to and above the temperature of the enameling furnace, 3,500 deg. F. (1,767 deg. C.), whereas the fireclay weakens, permit the construction of a furnace and muffle very much lighter. The carborundum floor may be 2 in. thick, whereas fireclay floors average 8 in., and the carborundum muffle may be 1½ in. thick, whereas fireclay must be 3 in. thick.

2. The high heat conductivity of the carborundum refractories permits the operation of the furnace with a much lower temperature in the combustion chamber and flues. The thermal conductivity of carborundum is seven times greater than fireclay, and as one-half the thickness is used fourteen times more heat is conducted through the walls of the muffle, thus permitting a temperature difference between flue gases and muffle of only 200 deg. F. (93 deg. C.). This one factor gives an average fuel saving of about 30 per cent, not to mention the lengthened life of the refractories.

3. This lightened construction permits a quicker heat—in fact five hours on an average from a cold furnace is common practice with carborundum muffles; and furthermore this permits a certain amount of temperature regulation not possible in clay muffles.

4. Lower combustion temperatures permit less bulky

constructions, conserving the heat. Another factor in the conservation of heat in modern furnaces is the use of insulating bricks, such as Silocel and Nonpareil.

5. Due to the high conductivity of the carborundum muffle the furnaces are designed to give and to deliver uniform temperatures throughout the muffle. Loading to the door is common practice, which gives an increased capacity of full 35 per cent. In one case a carborundum muffle tested with a Leeds & Northrup optical pyrometer by three people gave twenty readings running from 1,790 to 1,800 deg. F. (817 to 822 deg. C.), a variation of only 10 deg. and a temperature difference barely perceptible to the eye.

6. The output of a furnace is directly dependent on the temperatures which can be maintained within the muffle. This is easily accomplished in a carborundum muffle, due to its high thermal conductivity. A 30 per cent saving is the general average realized.

7. The life of the present-day furnaces, equipped for any system of firing and built in accordance with the latest specifications, using carborundum refractories, is apparently unlimited. In fact we have never yet had one burn out or need repairing so are not in a position to say definitely just how long they will last. One furnace was overheated to about 2,800 deg. F. without doing any damage to the muffle. It benefited the muffle by burning in the cement joints. This muffle after eight months' constant use, with shutdowns over Saturday and Sunday, is as true today as when installed.

8. Shutdowns over Saturday night and Sunday are regularly practiced by users of carborundum muffles, as five hours is sufficient time to heat up to working temperature and three hours is not uncommon with oil-fired furnaces. The fuel saving is very appreciable—in fact one user shows where he has saved the entire cost of the muffle in 120 days through fuel economy exclusive of the fuel saving due to being shut down over Sunday.

CONCLUSION

In conclusion we may summarize the comparison of the old and new type furnaces:

OLD	NEW
1. Excessive mass and character of refractories necessitates three to five days for the furnace to heat up. No definite temperature control can be practiced.	1. Light weight and refractories of high conductivity permit quick heating; five hours' time is general practice on coal, three hours on oil furnaces. Definite control of temperature is practicable.
2. Poor conductivity of refractories makes imperative high flue temperature, with resulting loss of fuel and shortened life of refractories.	2. High conductivity of refractories permits lower flue temperature, thus saving in fuel and lengthening of life of refractories.
3. Slow, careful heating, incurring large expense.	3. Rapid heating, with lessened expense.
4. High flue temperature, necessitating bulky construction to conserve heat.	4. Low flue temperature permits less bulky construction, and use of insulating material further conserves this heat.
5. Temperature difference between flue gases and muffle average 800 to 1,000 deg. F.	5. Temperature difference between flue gases and muffle average about 200 deg. F.
6. Uniformity of temperature within 10 deg. F. is unknown and full loading impractical.	6. Uniform temperature within 10 deg. F. is not uncommon and loading to door regularly practiced.
7. Fuel economy cannot be practiced.	7. Fuel economy over old type averages 30 per cent or more.
8. Life of muffle uncertain and short overheating is ruinous.	8. Life of muffle indefinitely long, overheating not injurious.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Hydrogen Peroxide.—In the manufacture of hydrogen peroxide solutions for commercial purposes, it has long been the custom to react upon barium peroxide, BaO_2 , with acids in the presence of water in various ways, thereby forming a barium salt and a solution of H_2O_2 . Acids forming normally insoluble barium salts, such as phosphoric acid and sulphuric acid, are usually employed. As is known, nitric acid may be employed for this purpose, since barium nitrate is but sparingly soluble particularly in the presence of any free nitric acid. In the formation of any of these insoluble or sparingly soluble barium salts, however, the difficulty is that it is hard to secure any complete conversion of the barium peroxide in the presence of small amounts of water—that is, under circumstances which will give a tolerably strong solution of hydrogen peroxide. ROBERT JACQUELET, of Catonsville, Md., suggests treating BaO_2 with a 2.5 per cent solution of HCl and then adding strong nitric acid which precipitates barium nitrate and releases an equivalent amount of HCl to attack a further quantity of BaO_2 . With proper operation there is no liberation of chlorine from the production of aqua regia and all the barium dioxide is utilized. The final result is a solution of hydrogen peroxide which may be of such a strength as to be the equivalent of 35 or 40 volumes of oxygen, this solution containing a small amount of dissolved barium chloride. The rest of the barium is found in the form of a crystalline nitrate, which may be subsequently utilized in known ways to reproduce barium dioxide and nitric acid. The barium nitrate, washed, pressed and dried, is a clean white powder. It may be sold as such. The hydrogen peroxide solution does not contain enough barium chloride in solution to interfere with its use for many purposes. If the operation is properly conducted, it will be stable and neutral. This solution may be treated in the usual way to obtain stronger solutions or to get pure hydrogen peroxide. (1,364,558; Jan. 4, 1921.)

Sulphuryl Chloride.—A good yield of sulphuryl chloride (SO_2Cl_2) is obtained by allowing sulphur dioxide and chlorine to react in the presence of one or more of the following catalysts: Esters which are formed from saturated aliphatic alcohols and saturated aliphatic acids containing only the elements C, H, O; triphenyl phosphate; tricresyl phosphate; eucalyptol, benzaldehyde; benzyl acetate. It is not necessary to use sunlight, ultra-violet rays or pressure with these catalysts. (1,364,738; THOMAS H. DURRANS, of Oxford, England, assignor to A. Boake Roberts & Co., Ltd., of London, England; Jan. 4, 1921.)

Method of Forming Refractory Articles.—In the manufacture of refractory shapes or abrasive stones from mixtures of silicon carbide or crystalline alumina and plastic clay it has been found necessary to use high pressure in order to extrude the mass through the dies. Unless the dies are lubricated, deformation and breakage occur. The problem of efficient lubrication may be met by mixing about 4 per cent of a saponified oil mixture known as petroleum grease with the abrasive-clay mixture before extrusion. (1,364,849; ALBERT H. ANDERSON, of Worcester, Mass., assignor to Norton Co.; Jan. 4, 1921.)

Purifying Benzanthrone.—In the production of benzanthrone—for example, by condensing anthraquinone and glycerine with the aid of sulphuric acid—the product obtained after removing water-soluble constituents is still impure. It contains unchanged anthraquinone, a red resinous substance and a material which is black when wet and brown when dry. According to LLOYD C. DANIELS of Buffalo, N. Y., halogen derivatives of the simple aromatic hydrocarbons, particularly chlorobenzene, are adapted for use

as selective solvents with this mixture. The crude benzanthrone press-cake is extracted with hot chlorbenzene. After filtering, the solution is cooled to about 15 deg. C., when the benzanthrone separates in quite pure form. When the benzanthrone is accompanied by considerable amounts of unchanged anthraquinone, it is sometimes difficult to effect a separation, owing to the formation of a eutectic containing about 11 to 12 per cent anthraquinone and 88 to 89 per cent benzanthrone. If, however, the anthraquinone is less than about 11 per cent, the separation is easily made. (1,365,024; assigned to National Aniline & Chemical Co., Jan. 11, 1921.)

Alcohols, Esters and Ketones From Petroleum-Cracking Still Vapors.—All phases of the process for utilizing the waste vapors from petroleum-cracking stills described in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 23, p. 1230, Dec. 22, 1920, are treated in a series of patents covering the research work done by CARLETON ELLIS, of Montclair, N. J.; MORTIMER J. COHEN, of New York; MATTHEW D. MANN, JR., of Roselle, N. J., and ROBERT R. WILLIAMS, of Chicago, Ill. The unsaturated hydrocarbons in the vapors are absorbed at about 20 deg. C. in H_2SO_4 of 1.8 sp.gr. The acid liquor may be treated to yield a variety of products. Alcohols (chiefly isopropyl) are obtained by diluting with water, which hydrolyzes the alkyl hydrogen sulphate. The alcohols are separated by distillation or by extraction with suitable solvents. By adding inorganic salts of organic acids, such as calcium or sodium acetate, to the acid liquor esters are found. Electrolytic oxidation of the acid liquors gives ketones and fatty acids. (1,365,043 to 1,365,053 inclusive; assigned, by mesne assignments, to Seth B. Hunt, trustee, Mount Kisco, N. Y., Jan. 11, 1921.)

Separating Nickel and Cobalt.—Nickel-cobalt ores of the type found in the cobalt district of Canada are brought into solution in the form of chlorides by any approved method. Iron is removed by treating the solution with chlorine, removing the excess of chlorine by means of air or otherwise, and then agitating with calcium carbonate or similar precipitant. If the chlorine has been completely removed, only iron is precipitated. The resulting solution, containing nickel and cobalt but free from iron, is then mixed with finely divided calcium carbonate (whiting, for example) and gaseous chlorine is bubbled through the pulp. If the solution is kept at a sufficiently low temperature, very pure black cobalt oxide is formed and practically all of the nickel remains in solution. (1,365,358; MARVIN J. UDY, of Kokomo, Ind., and OLIVER C. RALSTON, of Niagara Falls, N. Y., assignors to Hooker Electrochemical Co., Jan. 11, 1921.)

Phenols From Redwood.—Unlike most soft, resinous woods, redwood (*Sequoia sempervirens*) when destructively distilled gives a tar which contains large proportions of phenol and creosols. According to WALTER J. HUND, of Ross, Cal., one cord (4,000 lb.) of the light-wood from redwood stumps will give upon destructive distillation 50 to 60 gal. of tar (sp.gr. 1.11). This tar is then distilled. The fraction between 150 and 250 deg. C. is collected separately, giving from 20 to 25 gal. of middle oil, which is then treated with sodium hydroxide solution. Acidification of the alkaline extract gives 10 to 15 gal. of phenolic oils, which after fractionating and purifying yield 17 to 20 lb. crystalline phenol, 4 to 5 gal. cresylic acid and 2 to 3 gal. creosote. The absence of sulphur compounds and naphthalene simplifies the process. (1,365,407; Jan. 11, 1921.)

Recovering Volatile Solvents.—Vapors containing volatile solvents are treated with a mixture of sperm oil, lard oil, petroleum oil and alcohol. The solvent is subsequently separated from the absorbing agent. (1,365,791; SAMUEL S. SADTLER, of Springfield township, Montgomery Co., Pa.; Jan. 18, 1921.)

Glass.—A glass having a low coefficient of expansion and marked resistance to high and low temperatures is made from a batch consisting of a preponderance of silica, smaller amounts of boric oxide, alumina, sodium nitrate and sodium carbonate, and still smaller amounts of calcium carbonate and arsenic trioxide. (1,365,597; MAURICE A. SMITH, of Jeannette, Pa., assignor to McKee Glass Co.; Jan. 18, 1921.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Treating Gas Liquor to Form Fertilizers.—Gas liquor is freed from ammonium cyanide and sulphocyanide and rendered suitable for use as a fertilizer by adding yellow ammonium sulphide or sulphur or by treating it with air or other agent to separate sulphur from the sulphur compounds, and distilling the liquor. The cyanide is transformed into sulphocyanide which remains in the retort. (Br. Pat. 153,006; GES. FÜR LANDWIRTSCHAFTLICHEN BEDARF. and DR. I. R. MANDELBAUM, both in Munich. Jan. 12, 1921.)

Sodium Pentaborate—Boric Acid.—Boro-natro-calcite is treated with water or mother liquor and enough sulphuric acid to form calcium sulphate but without giving the mixture an acid reaction and the mixture is heated to 75 deg. C. and filtered. The filtrate is concentrated and cooled to obtain sodium pentaborate, Na_2O , $5\text{B}_2\text{O}_3$, $10\text{H}_2\text{O}$, and some boric acid remains in solution and may be recovered. The residue consists of calcium sulphate and unchanged boro-natro-calcite. It is treated with water or mother liquor and enough sulphuric acid to make the mixture acid, and is then filtered. Calcium sulphate remains on the filter, and boric acid is recovered from the filtrate. (Br. Pat. 153,007; not yet accepted; SCHOTT & GES., Jena, Germany. Jan. 12, 1921.)

Anthraquinone Derivatives and Dyes.—Condensation products, probably azomethine compounds, are obtained by heating 1-amino-2-methylantraquinone or its substitution products, or isomeric amino-2-methylantraquinone, or 2-methylantraquinone itself, with aromatic nitro compounds in the presence of alkaline reagents; primary aromatic amines may be added to the reaction mixture. The products are vat dyestuffs, and may be hydrolyzed by acids to give 1-aminoanthraquinone-2-aldehyde, or its substitution products or isomers, or anthraquinone-2-aldehyde, respectively. According to examples, condensation products are obtained by heating (1) 1-amino-2-methylantraquinone with nitrobenzene and potassium carbonate or with nitrobenzene, aniline, and potassium acetate or caustic soda; (2) 1-amino-2-methylantraquinone with *m*-nitroaniline, naphthalene, and potassium carbonate; (3) 1-amino-methylantraquinone with β -naphthylamine, nitrobenzene and potassium carbonate; (4) 4-*p*-toluido-1-amino-2-methylantraquinone, nitrobenzene, aniline, and potassium acetate; (5) 1:5-diamino-2-methyl-antraquinone, nitrobenzene, aniline, and potassium carbonate; (6) 3-amino-2-methylantraquinone, nitrobenzene, aniline, and potassium carbonate; (7) 2-methylantraquinone, nitrobenzene, aniline, and potassium carbonate. Examples are also given of the preparation of 1-aminoanthraquinone-2-aldehyde, 4-*p*-toluido-1-aminoanthraquinone-2-aldehyde, 1:5-diaminoanthraquinone-2-aldehyde, 3-aminoanthraquinone-2-aldehyde, and anthraquinone-2-aldehyde from these condensation products. (Br. Pat. 153,055; L. CASELLA & Co., Frankfort-on-Main, Germany. Jan. 12, 1921.)

Catalyst for Synthetic Ammonia.—Catalysts for use in the synthesis of ammonia are prepared by heating, preferably to a temperature below 500 deg. C. in a neutral atmosphere, simple cyanides of the metals, iron, nickel, cobalt and chromium, or complex cyanides of such metals, not containing a cyanide or alkali or alkaline earth metal, or in which the molecular proportion of such cyanide to the heavy metal cyanide is less than 2:1; by the use of these catalysts the synthesis of ammonia can be carried out at a temperature below 400 deg. C. and while using a pressure less than 100 atmospheres. Suitable initial compounds are ferrous cyanide, ferrocyanhydric acid, ammonium ferrocyanide, triammonium-potassium-ferrocyanide, potassium-ferrous-ferrocyanide (Everitts' salts), potassium-ferric-ferrocyanide (Williamson's violet). It is advantageous to add to initial materials not containing alkali or alkaline earth metals, a proportion of a compound of such metal, potassium nitrate for example, but the relative proportions here indicated must not be exceeded. (Br. Pat. 153,290; not yet accepted; NORSK HYDRO-ELEKTRISK KVAELSTOFKIESEL-SKAB, Christiania, Jan. 12, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Engineering Foundation and Industrial Research

Industrial research on a nation-wide scale, in which engineering organizations, universities, factories, individuals and private laboratories and other organizations are co-operating, is under way, according to the annual report of Engineering Foundation, prepared by the chairman, Charles F. Rand.

Describing the Foundation as a permanent national agency "for the furtherance of research in science and engineering, or for the advancement in any other manner of the profession of engineering and the good of mankind," Mr. Rand outlines a broad field of activity in which the Foundation, profiting by the lessons of the war, is working.

Highway research, experimentation in the fatigue phenomena of metals, mental hygiene in industry, industrial personnel research, psychological tests for engineering students, industrial education in training, and tests of mechanical equipment are among the projects which the Foundation's effort embraces.

The Foundation, according to Mr. Rand, now has an endowment of \$500,000. One anonymous gift of \$200,000 has been received and one individual, it is stated, has offered to give \$50,000 if nine other men would make equal gifts.

To avoid a possible deficit of \$16,000 by 1922 Edward D. Adams of New York assumed this contingent liability. Mr. Adams' liability has now been canceled, the financial requirements for the work in hand having been provided by the increased income from endowment. The Foundation is raising a fund of many millions to promote industrial research in America and hopes this year to reach the five million dollar mark.

Many new projects with design to foster research and thus help maintain this country's industrial supremacy are under consideration by Engineering Foundation. Among the specific researches suggested are: Cryogenics, particularly research in characteristics of gas mixtures in relation to liquefaction and separation of gases for industrial purposes; electrical insulation; colloidal lubricants and fundamental principles of lubrication; fundamental study of laws of crystallization of metals, atomic structures and other metallurgical problems; improvement of utilization of all kinds of fuels; principles of heat transfer; landslides; ceramics; hydraulics; industrial education and training; and social industrial engineering.

"Establishment and operation of a large hydraulic laboratory has been suggested as an appropriate undertaking for Engineering Foundation," declares the report. "It has also been proposed that the Foundation establish and conduct an Engineering Research Institute and Laboratory, to supplement the university training of promising research men, to provide place and means for research by engineers and inventors and for limited co-operative research by the industries, and to house models, apparatus and drawings of historic interest in connection with engineering research. The proposed laboratories could be made partly self-sustaining, but very large funds would be needed for their establishment and to supply the deficiencies in income.

"Another suggestion is that Engineering Foundation conserve research byproducts of engineering works. Engineering works frequently involve studies of special problems or in themselves constitute full-sized experiments, which could be made to yield important data. Sometimes the engineers in charge do not perceive the opportunity, not having been trained in research work. More often the possibilities are realized, but means, men and time cannot be used because of the commercial urgency for getting the project completed with minimum expenditure. Occasionally experimental work is undertaken in accordance with a well conceived plan,

but the exigencies of the main operation sooner or later interfere, or the information is gained but never made available; a greater familiarity with research methods and a broader conception of the problem could, with small additional expense, have secured much more valuable results and have made them more generally useful."

Kelly-Springfield Tire Co. Moves to Cumberland

After a survey of the entire country the Kelly-Springfield Tire Co. selected a 100-acre site along the Potomac at Cumberland, Md., for a model plant to have a capacity of 10,000 tires a day, including 1,500 truck tires. The business of the old plants at Akron, Ohio, Wooster, Ohio, and Buffalo, N. Y., will be transferred to the new factory, which will be ready for operation about April 1.

The new location is most satisfactory with respect to transportation, labor, raw materials, water and power. Three trunk line railroads serve the plant, and the location has a 10 per cent freight differential over Akron. An abundant coal supply is available within eleven miles.

The main building has a floor area of twenty acres. The main wing, 760 x 120 ft., two stories, is joined by five wings, each 305 x 60 ft. From receipt of raw material to shipment of finished product, one progressive movement is maintained in the process of manufacturing. Machinery includes three 90-in. calenders, the largest ever built, and two pumps with an approximate capacity of 6,000,000 gal. each. Power is furnished for six 750-hp. boilers. Future expansion is provided for in every phase of the layout.

The laboratory or experimental building, two stories, 300 x 55 ft., is said to be the only one in the industry in which a complete standard tire can be built. It contains the most modern equipment for chemical and mechanical development.

Plans for Chicago Convention of American Mining Congress

The twenty-fourth annual convention of the American Mining Congress and the National Exposition of Mines and Mining Equipment will be held in Chicago, Oct. 17 to 22 inclusive, with convention headquarters at the Congress Hotel. The Coliseum has been reserved for the exposition which will include exhibits of: Coal byproducts, chemicals, non-metalliferous substances, petroleum, oil shale, cement and cement products, raw and manufactured products, byproducts, smelting equipment, flotation and milling equipment.

Among the national conferences to be held during the convention will be those on Taxation, Production and Cost, Labor, Transportation, Standardization, Flotation, Gold Production, the Commercial Development of Byproducts, the Development of Non-Metalliferous Ores, National Finance, Mine Management and Handling of Men, Mineral Tariffs, etc. National leaders will discuss the present-day tendency toward government control of industry.

Crescent Refractories Co. Merger

Following the annual stockholders' meeting of the Crescent Refractories Co. of Curwensville, Pa., announcement was made of a merger of the George S. Good Firebrick Co. and the Clearfield Clayworking Co. with the Crescent Refractories Co.'s properties. Consolidation of these properties brings together three important Clearfield County fireclay and coal holding properties.

The output of the plants now operated by the corporation reaches 240,000 brick per day and marks another step forward in fireclay industry of this region.

New Jersey Clay Workers Defer Annual Meeting

At a meeting of the executive committee of the New Jersey Clay Workers Association and Eastern Section of the American Ceramic Society at Metuchen, N. J., March 5 it was voted to pass by the annual meeting of the organization, originally planned for January, but at which time it was impossible to arrange for the gathering. The next meeting will be held in June at Trenton, and it is proposed to make this midsummer gathering an important event. A committee has been appointed to arrange the details of the convention and fix a definite date. Another committee was selected to draft a set of new bylaws for the organization, to conform more closely to the constitution of the American Ceramic Society. Plans were also discussed for the new official publication of the organization, to be known as the *New Jersey Ceramist*, which will be issued quarterly. Charles Howell Cook, Trenton, chairman of the executive committee, presided at the meeting, with R. H. Minton, vice-chairman, acting in his stead prior to adjournment. Among those present were Abel Hansen, Perth Amboy, chairman of the association; Prof. George H. Brown, Rutgers College, secretary and treasurer; Charles A. Bloomfield, councilor, and representatives from the Mercer County and Raritan River sections.

Muscle Shoals Fight to Continue

Failure on the part of Congress to approve the \$10,000,000 item in the sundry civil bill intended for the continuation of the work on the Wilson dam at Muscle Shoals by no means ends the fight on this proposition. The development of Muscle Shoals and the disposition to be made of the nitrate plants at that point furnished the subject for acrimonious controversy throughout the greater part of the session of Congress which just has closed. Despite the approval of the Fixed Nitrogen Corporation bill by the Senate on Jan. 14, further progress of the measure was blocked in the House. This was comparatively easy because the amendments attached by the Senate would have made the proposed corporation almost unworkable.

CONTROVERSY OVER WILSON DAM APPROPRIATION

No sooner had the fight over the Fixed Nitrogen Corporation bill lulled than there arose the fight to appropriate for continuing work on the dam. The Committee on Appropriations of the House refused to include the item in this bill. Efforts to insert it on the floor were unsuccessful. The Senate, however, put the appropriation into the measure and retained it by decided majorities on two record votes. For a time it seemed that the sundry civil bill, carrying more than \$400,000,000, would fail of passage because of the controversy over the Muscle Shoals item. It was not until the closing hours of the session that the matter finally was settled when Senator Underwood withdrew his opposition, stating that there was nothing to be gained by causing the bill to fail. Each side to the controversy alleged that powerful lobbies were at work. The "fertilizer trust" and "the powder trust" were declared to be behind one lobby, while the other side said that the Alabama Power Co. was sponsoring the lobby which was supporting the item. Senator Underwood, in one of his statements on the floor of the Senate, said:

Seventeen million dollars was allocated for the purpose of building it; a large portion of that money has already been spent; and to abandon the project is to throw that money away. The testimony of the greatest engineers in America confirms the statement that this is an excellent undertaking; an undertaking that will safely return to the Government the money invested. It comes in the usual way, with an estimate from the Government to carry on the work; and the reason it is defeated is because a lobby, representing special interests, fighting for their own pocketbooks, regardless of the national defense and the interests of the national Government, have injected their fangs into the body of this legislation and torn this appropriation out of it. There is no man who knows the conditions that have confronted this proposal but that knows that is a fact. I will not call the names now, but if their names are wanted or if it is ever desired to investigate this question in the future I can name the men who have haunted the Capitol and the hotels in the city of

Washington lobbying against this proposition because they thought it might interfere with their private business, putting their own dollars above the integrity of the Government of the United States, its honor and its safety.

Senator Lenroot, of Wisconsin, was the most active opponent of the appropriation. He declared it to be a foray on the part of the Government into the field of private enterprise. He asserted that the Alabama Power Co. would be the chief beneficiary of the improvement.

Senator Underwood met this charge by stating that chemical and other industries would quickly locate at Muscle Shoals, once that the power became available, as they had done at Niagara Falls. He pointed out that at first there was much doubt expressed as to whether use could be found at Niagara Falls for 60,000 hp. His whole contention is that the development of this water power, which is capable of producing more power than is the present diversion on the American side at Niagara Falls, would be of immeasurable benefit to the country as a whole. He characterized it as unthinkable that the Government should throw away its investment of \$100,000,000 in view of the value of the project to the industries and in the matter of the national defense.

WORK ON DAM TO BE DISCONTINUED

In view of the failure to appropriate for continuing the work, the Corps of Engineers has issued instructions that all work be discontinued except in two cases where a great sacrifice would be involved were the work to stop at this time. At Jackson Island the work will continue until the cofferdam can be removed. There will remain about \$1,000,000 of the existing appropriation, which will be sufficient to look after the maintenance work until August, 1922, which is the earliest date that an appropriation is likely to be made available.

Chemical Warfare Service Criticized and Defended

The efforts of the War Department to develop chemical warfare prior to and following the armistice are criticized scathingly in one of the final reports by the select committee on expenditures in the War Department, of which Representative Graham of Illinois is chairman. An opposite position on chemical warfare is taken by the minority members of the committee.

In the majority report it is stated that nearly all the chemical warfare equipment which the United States used in the war was purchased from the Allies. This, it is said, applied to gas itself except in the latter months of the war. The report further states that American-made equipment did not reach France in time to help win the war.

The minority declares that the principal purpose of the majority is to "find something on which to base the criticism of the administration of our armies" and "is biased, erroneous and totally misleading" and "an example of ingratitude to those who bravely did their duty in the nation's great crisis." It is claimed that most of the criticism will fall of its own weight and that consequently no effort will be made to refute each of the allegations.

Civil Service Examination

An open competitive examination for pyrotechnic assistant is announced by the United States Civil Service Commission. A vacancy at Picatinny Arsenal, Dover, N. J., at \$1,872 a year, is among those to be filled from this examination. Applicants must have graduated from a four years' high school course (or its equivalent) and have had at least one year's experience along the line of pyrotechnic material. Experience in flying and acquaintance with the present equipment and devices used by the aircraft divisions of the War Department for signal work are desirable, but not essential. Applications will be received on Form 1312 until the hour of closing business on April 5, 1921.

Vanadium Plant Closed

The Chemical Products Co., of Denver, Col., engaged in the production of vanadium, with radium as a byproduct, has discontinued operations indefinitely. The cause given is the poor market for vanadium.

University of Wisconsin Chemistry Students to Make Their Own Chemicals Next Summer

To reduce the cost of chemicals needed for research work in various scientific departments of the University of Wisconsin, the chemistry department will give a new course in the manufacture of organic chemicals during the summer session under the direction of Prof. Glenn S. Skinner. There is only one other institution giving a course of this nature in the country, it is claimed.

All scientists in the university have been asked to leave their orders for chemicals with Prof. Skinner and as far as is possible these orders will be filled by his course.

Only eight advanced students will be admitted to the course and they will work from nine to ten hours a day and will receive about 40c. an hour for their work. Only the most promising graduates and upper classmen will be selected for the work, with the view of giving them intensive training in practical organic chemistry and experience in larger scale operations.

Co-operative Work on Ceramics Planned

An arrangement for co-operative work between the Bureau of Mines and several of the associations of brick manufacturers is being planned, it is understood. It seems probable that the Bureau of Standards also is to be a party to the contract. The proposition involves obtaining a substantial sum which will make possible experimentation in a number of the fundamental problems encountered in the making of brick. The associations concerned are: The Face Brick Manufacturers Association, the American Common Brick Manufacturing Association, the National Paving Brick Manufacturers Association, and the Hollow Building Tile Manufacturers Association.

British Optical Glass and Scientific Instrument Bill

A bill which contains the following features has been prepared by the British Optical Instrument Manufacturers Association for consideration in Parliament:

1. No optical glass or scientific instruments to be imported into this country for a period of, say, seven years, except under license.
2. Such licenses only to be granted in respect of goods which are not being made in Great Britain in the required quantities or of the required quality.
3. An expert licensing committee to be set up.
4. The optical instrument manufacturers are prepared, in order to guarantee reasonable prices, to submit to a control of profits.

New Sulphite Pulp Mill for British Columbia

H. S. Taylor, chief engineer of the Mead Engineering Co., has made an examination of the site and timber limits of the Prince Rupert Lumber Co. of Prince Rupert, B. C., which has recently formed a subsidiary company, known as the Prince Rupert Pulp & Paper Co. The company is arranging for the erection of a sulphite pulp mill at a cost of \$1,000,000 and it has made satisfactory arrangements with the city council with regard to taxation and water privileges.

British Columbia Oil Refinery to Resume Operations

C. M. Rolston, local manager for the Imperial Oil Co., Vancouver, B. C., has announced that arrangements have been made with California oil interests for the delivery of 600,000 bbl. of crude oil during the present year, and as soon as this oil commences to arrive the refinery at Ioco, near Vancouver, will be restarted. It was expected that the refinery would remain idle until June, when delivery of oil from Mexico had been arranged for.

Bureau of Standards Standard Samples

Renewal 5d of the exhausted standard iron sample C and renewal 10c of the exhausted standard bessemer steel 0.4 carbon are now ready for distribution with provisional certificates. The price of these standards is \$2 per 150 g. and samples will be shipped by parcel post C.O.D. upon application to the Bureau of Standards, Washington, D. C.

Pottery Firm Reduces Working Force

The Coors Pottery Co., of Golden, Col., manufacturer of chemical porcelain, recently laid off about sixty employees.

Book Reviews

ELECTROLYTIC DEPOSITION AND HYDROMETALLURGY OF ZINC. By *Oliver C. Ralston*; 201 pages, illustrated. New York: McGraw-Hill Book Co. Price \$3.

The author has concisely covered this interesting subject in an up-to-date little book. It is only in the last seven years that the electrolytic method has been a commercial success. As pointed out by E. P. Mathewson at the February meeting of the American Institute of Mining and Metallurgical Engineers (New York), electrolytic zinc production has now reached a stage where the furnace methods are doomed to extinction. While the electrolytic refining of zinc products and the precipitation of zinc from chloride solutions after chlorinating of zinc ores are discussed, most of the text is devoted to the electrolytic precipitation of zinc from sulphate solutions obtained by leaching roasted sulphide ores in dilute sulphuric acid. The latter method is the only one now on a commercial scale.

The author points out that the "roasting department is not merely a place in which zinc sulphide ores can be roasted to make zinc soluble, with little care or thought, but that careful control is necessary to prevent spoiling the ore for leaching purposes and in order to keep the plant supplied with just the right amount of sulphuric acid." The leaching and purification cycles are explained, and the steps required to remove the harmful impurities are covered at length. Detailed discussion is given of tank-house practice, including the effect of current density, temperature, acidity, circulation and impurities upon the nature of the zinc deposit and upon current and energy efficiencies. Much emphasis is rightly placed on the necessity of a pure electrolyte. Many references are given to various plants such as the Judge, the Anaconda (Great Falls) and the Trail plant in British Columbia. The two latter are the most important commercially and are referred to repeatedly by the author to explain details of operation and equipment. For those interested in this growing electrochemical process the book will serve as a ready and modern reference.

CHARLES H. ELDRIDGE.

* * *

PROCEEDINGS OF THE CHICAGO MEETING OF THE INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA. Industrial Relations Association of America, 564 Main St., East Orange, N. J. 592 pp. Price \$5.

The standard method of dealing with proceedings of technical societies is to put them on the bookshelf in the expectation of referring to them at some future time, quite frequently with the result that the paper turns yellow with age but the margins are unsullied with finger marks. But this volume of the proceedings of the Chicago meeting of the Industrial Relations Association of America simply refused to be handled in this way. Those who attended the meeting must have devoted at least four or more days' time to it and expended a corresponding sum of money. The unnamed person who compiled the record of the proceedings has contrived to commit to print so much of the spirit of the gathering and of the worthwhile discussion that for the price of a room for one night in a Chicago hotel anyone may have a fairly good knowledge of what happened. The reviewer has been carrying the volume around for weeks, knowing he should write his review but wanting always to get time to read some, because every page he had scanned had had something of interest. The principal speakers dealt with incentives and production, linking up the worker with the finished product, the foreman, organized labor, what the worker, and what the management wants. There were sectional meetings on banks, chemical industries, department stores, lumber, metal trades, packing industries, railroads and the steel industries. Of subject meetings, there were about thirty, running the gamut of the alphabet from Americanization to wage levels, so that everyone interested in industrial relations is sure to find something useful to him and to make him resolve that, if he can arrange it, he will attend the next meeting of the association.

T. T. READ.

Personal

Dr. JAMES ROWLAND ANGELL was elected president of Yale University by the Yale Corporation at its meeting on Feb. 20.

Dr. RAYMOND F. BACON spoke at the meeting of the Southern Naval Stores Association at Georgia Tech., Atlanta, Monday, March 14, on the possibilities of developing a pine oil and rosin industry with modern research.

ROBERT R. DREISBACH has resigned as chemical engineer with the Dow Chemical Co. to accept a position with The Barrett Co., Frankford, Pa., in connection with production and development work.

J. CLAIRE EVANS, vice-president of the Denver Fire Clay Co., was in New York City and other Eastern points recently on business.

• ANDREW M. FAIRLIE will lecture before the Franklin Institute, Philadelphia, on March 16 on "Recent Developments in the Manufacture of Sulphuric Acid."

E. A. GOODHUE, who has been a teaching fellow in chemistry at the California Institute of Technology for a year, has resumed his duties as instructor of chemistry at the University of Vermont, Burlington, Vt.

ROBERT W. HILTON, formerly manager of the Ault & Wiborg dye plant at Norwood, Ohio, is now in charge of the company's ink works.

JOSEPH S. REICHERT, for the past two years supervisor of production in the edible products department at the Ivorydale plant of Procter & Gamble Co., Cincinnati, Ohio, has accepted the appointment as professor of general and industrial chemistry at the University of Notre Dame, Notre Dame, Ind.

Dr. H. ROSSBACHER, who was formerly chief chemist of the Chicago Paving Laboratory, is now research chemist for the Western Electric Co.

C. C. SMITH, assistant secretary of the American Petroleum Institute, has resigned to accept a position as manager of the New York office of James B. Berry's Sons Co., Inc. Mr. Smith was made assistant secretary of the Institute at the time of its organization. Prior thereto he had been assistant secretary of the National Petroleum War Service Committee. In both positions he rendered conscientious and intelligent service, and leaves his work with the Institute with the esteem and confidence of the staff and the board of directors. Mr. Smith will continue to be assistant treasurer of the Institute.

E. R. WILES, who until last fall was in the employ of Cosden & Co. as assistant chemist in charge of analytical work, is now chief chemist of the Southern Oil Corporation at its refinery at Yale, Okla.

At the annual general meeting of the Faraday Society, London, the following officers were elected to serve for the coming year: President, Prof. A. W. Porter; vice-presidents, W. R. Cooper, Prof. C. H. Desch, Dr. J. A. Harker, Emil Hatschek, Prof. T. M. Lowry, Dr. E. H. Rayner and Dr. G. Senter.

Obituary

JOHN D. PENNOCK, general manager of the Solvay Process Co., died suddenly on March 11 at Syracuse, N. Y., upon his return from a vacation in South Carolina. Mr. Pennock was born at Morristown, Vt., in 1860, was graduated from Harvard in 1883, and was an instructor in chemistry there during the following year.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, March 14, 1921.

The recent acquisition of German territory and industries by the Allies has caused an increased call for several important chemicals which had recently been bought from Germany. It now seems probable that the Allies will control German exports and seize a substantial amount of them and consumers who thought that they had bought wisely from Germany at lower prices than procurable here were greatly perturbed over this action. Among the items in demand were *bichromates*, *oxalic acid*, *caustic potash*, *muriate of potash* and *chlorate of potash*.

Aside from this sudden change the chemical industry in general has reflected the economic conditions which prevail in every important trade at present. The movement, while fair in some commodities, has been sluggish in others and buyers still are contented to operate on a conservative basis pending improvement, which they feel is not a long way off. While there has been some increase noted in the sales of large producers, the demand is far below normal and rumors are current regarding a further decrease in production. The cost of some of our basic chemicals is now so low that further downward revisions in prices without a proportionate reduction in the cost of manufacturing might prove quite ruinous.

Pressure of resale material has been felt at intervals and the need of ready cash has occasionally caused dealers to sacrifice values to insure an immediate sale. It seems reasonable to believe that with the restricted production now in effect and the gradual absorption of spot stocks the situation will eventually right itself. Some inquiries have reached the market from textile mills, but it seems that tanneries are still idle buyers. Paper mills have taken on bleaching powder for near-by and future shipments. Soap-makers have shown an added interest in oils and fats, but have not been purchasing chemicals to any noticeable extent. Glassmakers appear to be well covered by standing contracts and the call from these interests is sufficient to keep dense soda ash in light supply.

EXPORT BUSINESS DULL

The export business remains dull. Inquiries for miscellaneous chemicals are in the market quite frequently, but the deflation of exchange rates has prevented business. Another great barrier to foreign trade is the credit situation. Foreign buyers require ninety days credit and our banks are unwilling to discount these drafts. Supplies of chemicals in foreign hands are not believed to be heavy. Liquidation has been going on in foreign countries as well as in America.

There is a strong feeling of confidence in the new administration at Washington. Industry is looking forward to a sound constructive policy and an expansion of confidence ought to be reflected in exchange rates. This in itself should serve as a great remedy to the present depression.

Domestic prime white *arsenic* is quoted at 10@11c. per lb., according to quantity and time of delivery. Resale lots of foreign material have reached the market at somewhat under this figure, while prompt shipments from abroad were quoted at 8c. per lb. Prominent sellers are looking for a marked improvement in the consuming demand, as some of the leading insecticide manufacturers have not covered their requirements. Sales of *muriate of potash* have been reported from \$60@\$70 per ton, basis 80 per cent, delivered. The inside price records a decline and rumors were heard that sales had been made at further price reductions. Competition between foreign and domestic sellers is having a depressing influence and the tendency of price is described as easy.

Resale transactions in solid *caustic soda* during the week were reported at figures ranging from \$3.60@\$3.75 per 100

lb. Rumors were current that isolated lots under stress pressure sold below the inside price, but sellers as a rule gave \$3.60 as the minimum trading figure for spot material. Although an occasional carlot of *soda ash* was sold at \$2 per 100 lb., most dealers were not inclined to shade \$2.10 and some sellers were asking up to \$2.15. The inquiry for double bags has remained very quiet and the market was quoted nominal at \$2.10 per 100 lb. Ash in barrels seemed to be most in demand and sales were reported as high as 2½c. per lb. Offerings were very light in all directions and the tone of the market appeared quite firm. Foreign *prussiate of soda* had a depressing influence on spot quotations and prices declined from 15c. to 14c. per lb. The buying power was not accentuated and consumers preferred to operate on a hand-to-mouth basis. Factors in domestic prussiate were not eager to quote owing to the quiet extent of inquiries, but intimated they would meet any competition if the occasion required.

Sharp reductions were announced in prices on *methanol* by producers. Pure methanol is now quoted at \$1 per gal. in tank cars, the 95 per cent at \$1.12 per gal. in barrels, and the Columbian spirits at \$1.35 in barrels. *Ethyl alcohol* is in easy supply at \$4.75@5 per gal. Denatured is moving in small lots, while prices are somewhat irregular, with a range from 42@54c. per gal., depending on the formula.

COAL-TAR PRODUCTS

Some improvement in trading could be noticed in the coal-tar products market during the past week. The degree of improvement is not very great, however, as consumers still look for lower prices and will come into the market only for short time supplies. Prices have shown an easy tendency and shading is practiced in various quarters. Intermediates have moved in better volume and prices have shown no radical changes. Consumers of *aniline oil* seem to be in good supply and while stocks are plentiful prices are fairly steady at 22@26c. per lb. A fair movement is reported in *beta naphthol* at 34@40c. per lb. The market on *paranitraniline* is not very active, but prices are steady at 90c.@\$1.05 per lb. The crude products, such as *benzene*, *naphthalene* and *phenol*, have shown a greater activity of late. *Naphthalene flake* prices are steady at 8½@9c. per lb. and trading is said to be in fair volume in most quarters. There is little activity in the market for *para-dichlorbenzene*. The consuming demand is of a light routine nature and prices are holding steady on a basis of 15@20c. per lb. The demand for *diphenylamine* continues along routine lines and for quantities only sufficient to meet present needs. There has been no recent change in the price level at 60@70c. per lb., depending on quantity.

RUBBER

The tone of the crude rubber market was slightly easier, and while intimations were made that prices could have been shaded in some quarters no actual changes were recorded. *Spot ribbed smoked sheets* were offered freely at 17½c. per lb., but inquiries were few and commanded but little attention. *First latex spot* was named at 19½c. per lb. asked and 19¼c. on firm bids. Futures on *ribs* were subject to little demand. April, May, June sellers were asking 19¼c., but as far as could be ascertained no business was done. July-September was also a dull affair and remained quoted at 22½c. per lb. October, December sellers were few. Trading in general during the week was of an extremely small volume and little encouragement was offered in any direction.

WAXES

The market for crude *beeswax* was quiet, but prices held fairly steady basis. African crude was quoted from 17@19c. per lb., depending upon quality and seller, with the Brazilian at 23@25c. per lb. Refined beeswax was nominal at 27@30c. per lb. Prices on *carnauba wax* varied but little during the past week, reflecting a steady position at primary markets. The higher grades on the spot are in rather light supply and prices named are more or less nominal. Offerings of the common sorts are plentiful and slight irregularity in prices is named by importers. For No. 3 North Country quotations held at 18@19c. per lb.

Demand for *Japan wax* was routine only, but with importations smaller prices were well maintained at 19@20c.

per lb. The tendency of prices in the market for *paraffine wax* was downward during the past week. New business placed was not up to expectations, the export inquiry being particularly slack. Refiners offered scale wax, 124-126 deg. melting point, in carlots for immediate shipment at 2½c. per lb. and it was reported that actual business had been placed at this figure. Fully refined, 130 deg. melting point, was nominal at 6c. per lb.

The Iron and Steel Market

PITTSBURGH, March 11, 1921.

An analysis of the American Iron and Steel Institute's report covering the steel ingot production of thirty steel companies in February indicates that the rate of steel ingot production by the whole industry in February was about 25,200,000 gross tons per annum, or about 48 per cent of the actual productive capacity. The Steel Corporation operated at an average slightly above 75 per cent and the independents at slightly above 25 per cent. The Steel Corporation's rate this week is lower, about 60 per cent, while the independents are probably a trifle under 25 per cent.

If all that has occurred in production were to be ascribed to the influence of the price-cutting campaign inaugurated by independents early in February it could be said that the independents did not improve their position, while the Steel Corporation lost very considerably in production. The corporation operated at about 90 per cent in January, while the independents operated at about 28 per cent. However, both the corporation and the independents were in line for decreasing production if prices had remained steady, as there was very little buying and old orders were being worked out. The fair conclusion is that the price cutting saved the independents from any considerable decrease in operations, while it caused the Steel Corporation's operations to decrease at a greater rate than would otherwise have been the case. All observation tends to show that the Steel Corporation has not lost any customers to independents by the price cutting, but that its customers have in many cases been moved to curtail or shut off their receipts of steel from the corporation.

STEEL CORPORATION TONNAGE

The Steel Corporation's unfilled tonnage obligations at the end of February, as reported yesterday, amounted to 6,933,867 tons, the smallest amount since late in 1919. The de-

crease during February was 639,297 tons, this comparing with decreases of 574,958 tons in January and over 800,000 tons in each of the two preceding months. The February decrease was 51 per cent of the month's capacity, while shipments in February may be estimated at 75 per cent of capacity, making the net bookings the difference between these, about 24 per cent. The net bookings would be made up of total bookings minus cancellations, but there is no reason to suppose there were any cancellations of consequence. That matter seems to have been taken care of in the Dec. 31 statement. That the corporation had any bookings when the independents were cutting prices and the corporation was rigidly adhering to the price schedule is explained by the fact that the corporation's customers value a place on the corporation's order books. In 1920 their allotments saved them a great deal of money on account of independents having advanced their prices far above the corporation level.

STEEL PRICES

Perhaps there is a new trend in steel prices. Certainly the independent steel market is not moving in regular form pursuant to there having been a break a month ago. Prices should either be continuing to sag at this time or should have developed a definite level showing signs of strength, and neither of these is the case. On the whole the lowest prices being done by independents are not noticeably lower than those of a week ago, while there certainly is no market stability. Some extreme low prices that were spoken of a week or two ago as a possibility are not now mentioned, as, for instance, 1.85c. for bars.

As to the attitude of steel buyers, that is perfectly clear. The buyers as a class are not interested. It is not a case of prices not having gone down sufficiently to suit buyers, for the buyers do not know at what price they could place really attractive orders. The mills have been quite willing to listen to bids, whether or not they would accept them, but the bids have not been made. In circles outside the steel industry it is being suggested that the Steel Corporation should reduce its prices, there being the apparent assumption that this would bring buyers into the market. There is no basis in steel market experience for any such assumption.

As to the attitude of the independent steel producers, there is some disposition to withdraw from the price-cutting operation, though there is no definite movement back to the old, or Steel Corporation, schedule. There is merely a chance that such a movement may occur.

Finally, as to the Steel Corporation's attitude, the corporation has not reduced prices or wages. It has been well settled that the corporation would not reduce one without the other. The corporation refuses to be influenced by what the independents have done. It elects to be independent.

ELIMINATION OF THE 12-HOUR WORKDAY

From Judge Gary's statement made early this week it may be deduced as a probability that the Steel Corporation will act upon the wage matter in about thirty days and that the action will involve elimination of the 12-hour workday. If this long-expected change is made the balance of probability is that there will not be straight substitution of an 8-hour shift. There have always been strong objections to that course, two of the objections being that eight hours is too short a time from start to finish, and that most of the men are not in continuous employment during their hours on duty. The difficulty has been to arrange for continuous operation with a system that lies between straight two shifts and straight three shifts. That a compromise ground is being sought is evidenced by the fact that the committee in charge of the matter, composed of no less than the presidents of subsidiary companies, has been hard at work and cannot yet report.

There is a possibility that the corporation may make a change in rates and working conditions that will not reduce the wage cost of producing a ton of steel, and in that event price reductions would not necessarily accompany the change.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

SAND SPRINGS—The Oklahoma Tanning & Mfg. Co., has acquired local property consisting of two factory buildings with adjoining site, and will remodel and equip the structures for a leather tannery. It is proposed to develop a total output of about 5,000 hides per day, with necessary plant extensions as required. Uley Holderman is president.

BATESVILLE—The White River Manganese Co., 567 Bway, Gary, Ind., will install considerable new machinery in connection with its development work on manganese properties at Batesville. Preliminary work has been commenced on a tract of over 100 acres, and it is proposed to establish a plant with daily output of about 50 tons. Washing and concentrating machinery will be purchased at an early date. William G. Rinehart is president and manager.

Florida

MIAMI, FLA.—The Moore Haven Sugar Corp., recently organized with a capital of \$1,000,000, has taken over the plant and property of the Moore Haven Syrup Co., Moore Haven, Fla., consisting of a total of 8 mills on a tract of 450 acres of land. The plant will be remodeled to manufacture clarified raw sugar and byproducts, and new machinery will be installed for this purpose. It is proposed to develop the mills to a point of consumption of about 600 tons of sugar cane per day. The work, including machinery installation, is estimated to cost in excess of \$500,000. E. C. George, Moore Haven, is president and general manager; John C. Grambling, Miami, is secretary and treasurer.

Indiana

KOKOMO—The Kokomo Steel & Wire Co., Citizens' Trust Bldg., has awarded a contract to the Indiana Bridge Co., Muncie, for the rebuilding of its steel works, recently destroyed by fire with loss estimated at about \$300,000, including machinery.

ALEXANDRIA—The Lippincott Glass Co., Greenwood Bldg., Cincinnati, Ohio, manufacturer of chimneys, globes, etc., has commenced the construction of a large tenpot furnace at its plant at Alexandria. It is proposed to place the new furnace in operation at the earliest possible date.

Kentucky

LOUISVILLE—The Standard Sanitary Mfg. Co., Pittsburgh, Pa., manufacturer of sanitary earthenware products, is completing plans for the erection of a new unit at its Louisville works, to be 1 story, 75 x 200 ft., to be used for the manufacture of chinaware specialties, as handles, fittings, etc. It is proposed to have the pottery in operation at an early date.

Louisiana

ST. ROSE—The Petroleum Export & Import Corp., subsidiary of the Carson Oil Co., 29 South La Salle St., Chicago, Ill., is perfecting plans for the erection of a number of buildings on local site for a new oil refinery. The plant will cost about \$500,000, with equipment. A battery of 20 storage tanks will be constructed, contract for which has been let to the William Graver Tank Corp., Chicago, Ill. A power plant, boiler house, pumping plant, machine shop and mechanical buildings will also be constructed. A factory for the manufacture of tin containers will be erected in conjunction with the works. Edward B. Carson is president of the parent company.

Maryland

BALTIMORE—The Prudential Oil Corp., Curtis Bay, is perfecting plans for the construction of its new local oil refinery, estimated to cost close to \$1,000,000 with machinery. As preliminary to the work the

company has filed plans for the construction of a series of steel oil tanks, with total capacity of about 275,000 bbl. The tankage system will cost about \$75,000.

Massachusetts

HOLYOKE, MASS.—The Julid Paper Co. is reported to be planning for the rebuilding of the portion of its works destroyed by fire March 4, with loss estimated at \$200,000.

NATICK—The Natick Tag & Label Co. has acquired the plant of the Natick Machine Co., Royal Arcanum Bldg., and will use the property in connection with its operations.

New Jersey

NEWARK—Keiner & Co., Inc., recently incorporated with a capital of \$125,000, has acquired the plant of the Newark Paving Co., comprising a series of 1-story buildings on a tract bounded by Adams, Parkhurst and Harper Sts. and Ave. F, for the establishment of a new plant for the manufacture of tanning extracts. The property aggregates about 20,000 sq. ft., and about one-half of this space will be utilized at the present time. Equipment will be installed at an early date, including a leather finishing department. The lease covers a period of five years with option to purchase. The company is headed by Erich G. Keiner, Wilmington, Mass.; Irving Willner, 18 Waverly Ave., and Jacob Lubetin, 164 Market St., both of Newark.

GARWOOD—The American Amino Corp. is operating at its new plant at Matawan, N. J., and will produce a line of intermediates at this works. It will be operated in conjunction with the Garwood factory.

MAURER—The Barber Asphalt Paving Co., Land Title Bldg., Philadelphia, Pa., has filed plans for the erection of a new brick and steel building at its local asphalt works to cost about \$101,000, to replace one of the sections of the plant recently destroyed by fire. Construction is under way on another large building at the refining plant to cost about \$306,000; contract for this latter structure was let to the White Construction Co., 95 Madison Ave., New York.

New York

BROOKLYN—The Novocal Chemical Co., 2923 Atlantic Ave., is taking bids for extensions and improvements in its plant to cost about \$35,000. The company has recently filed plans for extensions and betterments in another department of the works to cost \$110,000. William C. Winter, 100 Van Sickler Ave., is architect.

BROOKLYN—The J. Lackner Co., 308 Seventh Ave., Long Island City, manufacturer of paper specialties, has filed plans for extensions and improvements in its plant to cost about \$18,000.

TONAWANDA—The J. Spaulding & Sons Co., 484 Broome St., New York, manufacturer of fiber products, has preliminary plans under way for the erection of a new plant at Tonawanda, to consist of a series of 1-story buildings, with one 5-story structure. The factories will be 105 x 300 ft., 60 x 180 ft., and 50 x 200 ft. George F. Hardy, 309 Bway., New York, is engineer.

North Carolina

MORGANTOWN—The Burke Extract Co., manufacturer of tanning extracts, is planning for a number of extensions in its plant. It is proposed to install new machinery to increase the present output from 80 to 160 bbl. of tanning materials per day.

WAYNESVILLE—The Natural Abrasive Mining Co. of America, recently organized, has plans under way for the development of extensive properties in this section. The company has secured options on about 700 acres of land, containing mica, feldspar, abrasives and other minerals, and will conduct operations in these materials. A number of small plants in this district will be taken over and enlarged.

Pennsylvania

PITTSBURGH—The Standard Sanitary Mfg. Co., manufacturer of sanitary earthenware products, has filed plans for the erec-

tion of a new 2-story brick and steel addition on Ontario St. near Preble Ave., Northside, to cost about \$50,000.

CURWENSVILLE—The Crescent Refractories Co., with local refractory manufacturing plant, has been merged with the George S. Good Fire Brick Co. and the Clearfield Clay Working Co., Clearfield, Pa., both manufacturers of similar products. The total output of the present plants will be about 275,000 refractory bricks and shapes per day.

GREENSBURG—The McKee Glass Co. has resumed production at its plant after a shutdown for about two months. It is proposed to increase production until normal is reached.

Texas

WACO—The Waco Producers' & Refining Co. has awarded a contract to R. E. Whitlock, Dallas, Tex., for the erection of a new refinery at South Bosque, near Waco, to cost about \$75,000. It is planned to develop a daily output of about 300 bbl.

RANGER—T. S. Hudleston and associates have organized a new company to build a plant near Belton, Tex., for the manufacture of crockery and other pottery products. The company has acquired a site for the plant, as well as neighboring kaolin properties for raw material supply. The factory is estimated to cost about \$200,000 with machinery.

MEXIA—The Mexia Refining Co. is planning for the construction of a new oil refinery with initial capacity of about 1,000 bbl. per day.

FREEPORT—The Freeport Sulphur Co. is planning for the construction of a new asphalt plant, to be operated in conjunction with its present local works.

HOUSTON—The Humble Oil & Refining Co. has arranged for note issue of \$25,000,000, the proceeds to be used in part for proposed extensions, betterments, operations, etc. W. S. Farish is vice-president.

SAN ANTONIO—C. L. Witherspoon and associates are planning for the erection of a new oil refinery in the vicinity of Somerset, Tex., with daily output of about 1,000 bbl. A site has been selected.

Virginia

PEARISBURG—The Tazewell Brick Co. is planning for extensions and improvements in its plant at Tip Top, Va. The company was recently incorporated with a capital of \$75,000. C. L. King is president.

STAUNTON—The Farmers' Marl Co., recently organized with a capital of \$150,000, is planning for the development of extensive marl properties in this section. A plant will be established and equipped for a daily output of about 40 tons of material. The company holds leases to about 40 acres of land. C. J. Johnne is president.

Washington

SPOKANE—The Washington Brick, Lime & Sewer Pipe Co. has acquired a tract of land on Monroe St., totaling about 65,000 sq. ft., as a site for the erection of a new brick plant. It is estimated to cost about \$75,000. Construction will be inaugurated at an early date.

New Companies

THE INTERNATIONAL CHEMICAL CO., 13 West Saratoga St., Baltimore, Md., has been incorporated with a capital of \$150,000 to manufacture chemical products. The incorporators are S. F. Acree, Wade A. Gardner and Carlyle Barton, Baltimore.

THE L. G. NESTER CO., Clayville, N. J., has been incorporated with a capital of \$50,000 to manufacture surgical glassware specialties. The incorporators are Lyman G. Nester, William H. Hennis and A. C. Rosenberger, Clayville.

THE PHENIX MINERAL PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of \$100,000 to manufacture brick, ceramic tile and glassware products. The incorporators are J. and A. Levy, and H. M. Johnson, 26 Liberty St.

THE JOHN C. DOW LEATHER CO., Boston, Mass., has been incorporated with a capital of \$50,000 to manufacture leather products. The incorporators are Charles W. Dow, Frederick S. Murphy and John C. Dow, 117 Eastern Ave., Lynn, Mass.

THE NORTH AMERICAN PETROLEUM CO., 2 West South Water St., Chicago, Ill., has been incorporated with a capital of \$100,000 to manufacture oil products. The incorporators are Philip LaMantia, Joseph V. LaMantia and W. E. Gladstone.

THE ATLANTIC RUBBER ACE Co., New Brunswick, N. J., has been incorporated with a capital of \$100,000 to manufacture rubber goods. The incorporators are Louis J., Edward L. and Conrad Sebott, 390 George St.

THE GARRETT PAPER CORP., Newton Square, Pa., has been incorporated with a capital of \$30,000 to manufacture paper goods. C. E. Hand, Wyncote, Pa., is treasurer.

THE MARBO METAL PRODUCTS CORP., Calvert Bldg., Baltimore, Md., has been incorporated with a capital of 10,000 shares of stock without par value. The incorporators are Francis H. Stevenson, James A. Curtis and William H. Hill.

THE UNITED STATES PULP PRODUCTS CORP., Boston, Mass., has been incorporated under Delaware laws with a capital of \$1,750,000 to manufacture pulp and paper products. The incorporators are Lindsey Hooper, Boston; Ernest L. Fox and L. G. Rowe, Newark, N. J.

E. BURNHAM, INC., 138 North State St., Chicago, Ill., has been incorporated with a capital of \$250,000 to manufacture chemicals and byproducts. The incorporators are Gerald, M. and Edward Burnham.

THE BALDWIN PAPER MILLS, INC., New York, has been incorporated with a capital of \$10,000 to manufacture paper goods. The incorporators are S. S. Himmel, H. Brownstein and H. E. Goldberg, 261 B'way.

THE EASTERN OIL & REFINING Co., Indianapolis, Ind., has been incorporated with a capital of \$45,000 to manufacture refined oils. The incorporators are N. E. Carter, Daniel Hecker and B. H. Campbell, Indianapolis.

THE UNION CHEMICAL WORKS, 10 New York Ave., Union Hill, N. J., has filed notice of organization to manufacture chemicals and byproducts. The company is headed by Joseph B. Kreste.

THE BLANDFORD PAPER BOX CORP., Elmira, N. Y., has been incorporated with a capital of \$100,000 to manufacture paper boxes and other containers. The incorporators are Herbert Blandford, Harold S. Mathews and Emil Jackson, Elmira.

THE OKLAMAR Co., 300 Continental Bldg., Baltimore, Md., has been incorporated with a capital of \$100,000 to manufacture refined oils and kindred products. The incorporators are F. Craig Morton, Horace T. Smith and H. Webster Smith.

THE KENT AVENUE CHINA Co., Brooklyn, N. Y., has been incorporated with a capital of \$100,000 to manufacture chinaware, pottery, etc. The incorporators are R. Deibel, J. H. Schwartz and M. Bergman, 1245 46th St.

F. PETER DEUGLER, INC., 190 North State St., Chicago, Ill., has been incorporated with a capital of \$85,000 to manufacture chemicals and byproducts. The incorporators are J. C. Alten, C. C. Taylor and F. Peter Deugler.

THE CRYSTAL SHADE Co., Wheeling, W. Va., has been incorporated with a capital of \$15,000 to manufacture porcelain goods. The incorporators are G. D. Foller, Harry E. Simpson and Frank McConnell, Wheeling.

THE PRUDENTIAL ALLOYS & CHEMICAL Co., 14 Lewis St., Newark, N. J., has filed notice of organization to manufacture chemicals and affiliated products. The company is headed by Herman Rubin, 56 Boyd St.

THE ROSE CLAY PRODUCTS CORP., Philadelphia, Pa., has been incorporated with a capital of \$100,000 by Ernest R. and A. R. Rosse, Philadelphia; and Joseph R. Rosse, Essington, Pa.

THE VERIBEST CHEMICALS, INC., New York, N. Y., has been incorporated with a capital of \$100,000 to manufacture chemicals and byproducts. The incorporators are S. Lyons, E. F. Rapp and B. M. Kaplan, 23 West 112th St.

THE NON-ALCOHOLIC PRODUCTS Co., 9 South 22d St., Irvington, Newark, N. J., has filed notice of organization to manufacture chemicals and affiliated products. William L. Zucker, 31 Ridgewood Ave., heads the company.

THE DI BELLA GLASS Co., Scott Depot, W. Va., has been incorporated with a capital of \$10,000 to manufacture glassware. The incorporators are John Di Bella, T. Pine and E. A. Taylor, Scott Depot.

THE GAUER-LAWSON Co., 1202 Webster Ave., Chicago, Ill., has been incorporated with a capital of \$5,000 to manufacture rubber goods. The incorporators are George A. Gauer, Frank B. Lawson and John F. Rau.

THE JOSEPH PETRY PRINTING INK Co., New York, has been incorporated with a capital of \$25,000 to manufacture printing

and marking inks. The incorporators are J. G. Snyder, A. W. Vanness and Joseph Petry, 261 West 27th St.

THE UNIVERSAL SPECIALTY Co., 975 West Side Ave., Jersey City, N. J., has filed notice of organization to manufacture chemical products. The company is headed by Gustav Levy.

THE UNITED STATES BOILER COMPOUND Co., 180 North Dearborn St., Chicago, Ill., has been incorporated with a capital of \$10,000 to manufacture boiler compounds for water treatment. The incorporators are M. Black, M. and John L. Fox.

THE E. M. JAVITZ & SON CORP., New York, N. Y., has been incorporated with a capital of \$10,000 to manufacture chemicals and affiliated products. The incorporators are J. Schanzenbach, A. and E. M. Javitz, 1 Hudson St.

THE PENN PAINT Co., Pittsburgh, Pa., has been incorporated with a capital of \$25,000 to manufacture paint, oils, varnish, etc. C. D. Miller, 732 Whitney Ave., Wilkesburg, Pa., is treasurer.

THE H. & J. BREWER Co., Springfield, Mass., has been incorporated with a capital of \$96,800 to manufacture chemicals and affiliated products. The incorporators are Clinton E. Bell and G. E. Sheldon, Springfield, Mass.; and V. A. Converse, Longmeadow, Mass.

THE MCLEOD LEATHER & BELTING Co., Greensboro, N. C., has been incorporated with a capital of \$200,000 to manufacture leather products. The incorporators are E. D. Broadhurst, Greensboro; W. T. McLeod and J. A. Schachner, both of Charlotte, N. C.

THE BISON PLATE & WINDOW GLASS CORP., Buffalo, N. Y., has been incorporated with a capital of \$100,000 to manufacture glass products. The incorporators are G. F. Wallace, F. E. Trautman and E. J. Lienert, Buffalo.

THE CHIANAL CHEMICAL Co., 52 Hartford St., Newark, N. J., has filed notice of organization to manufacture special chemical products. The company is headed by John E. O'Sullivan.

THE OLYMPIC DISC RECORD CORP., 101 East Fayette St., Baltimore, Md., has been incorporated with a capital of \$2,500,000 to manufacture composition products. The incorporators are D. L. Warner, Evan D. Llewellyn and Leslie E. Mihm.

THE AIMES MFG. Co., Jersey City, N. J., has been incorporated with a capital of \$100,000 to manufacture chemicals, byproducts, drugs, etc. The incorporators are William D. P. Aimes and S. Walter Silverman, Philadelphia, Pa.; and Irving Solm, Bayonne, N. J.

Capital Increases, Etc.

THE GREAT EASTERN PAPER Co., INC., 377 Broadway, New York, N. Y., has filed notice of increase in capital from \$30,000 to \$100,000.

THE CELLULOID Co., 290 Ferry St., Newark, N. J., is arranging for an increase in capital from \$6,000,000 to \$10,098,000.

THE FRONTIER BRASS FOUNDRY, 818 Elmwood Ave., Niagara Falls, N. Y., has filed notice of change of name to the Frontier Bronze Corp.

THE VICTOR CHEMICAL WORKS, 343 South Dearborn St., Chicago, Ill., has filed notice of increase in capital from 55,000 shares to 100,000 shares of stock, no par value.

THE ATLANTIC PAINT Co., Charleston, S. C., has filed notice of increase in capital from \$20,000 to \$75,000.

THE REMINGTON PAPER & POWER Co., Watertown, N. Y., has filed notice of change of name to the Hanna Paper Corp., at the same time increasing its capital from \$300,000 to \$2,500,000 for expansion.

THE C. G. WINANS Co., 126 Frelinghuysen Ave., Newark, N. J., manufacturer of salt products, has filed notice of increase in capital from \$80,000 to \$160,000.

THE VULCANIZED RUBBER Co., 251 Fourth Ave., New York, N. Y., has filed notice of dissolution of its New York charter, to organize under Maine laws with a capital of \$1,500,000.

THE E. J. KNAPP CANDLE & WAX Co., Free St., Syracuse, N. Y., has filed notice of increase in capital from \$317,500 to \$1,025,000.

THE INTERNATIONAL FOLDING PAPER BOX Co., 396 South Second St., Brooklyn, N. Y., has increased its capital from \$50,000 to \$250,000.

ELBERT & Co., 27 William St., New York, N. Y., manufacturer of oils, has increased its capital from \$50,000 to \$100,000.

Industrial Notes

CELLULOID ZAPON Co. announces the opening of a Philadelphia office at 520 Walnut St., in charge of B. O. Clausen.

MEIGS, BASSETT & SLAUGHTER, INC., consulting engineers, of Philadelphia, are making a survey of the Old Hickory plant near Nashville, Tenn., for the Nashville Industrial Corp.

ADAMSON MFG. Co., East Palestine, O., has added a new department for manufacturing all kinds of storage, pneumatic and pressure tanks, welded pipe, battery casings, evaporators, condensers and a large line of arc-welded products adaptable to the chemical industry.

THE FANSTEEL PRODUCTS Co., INC., announces that since Jan. 27, 1921, the main office has been located at North Chicago, Ill.

THE JOSEPH DIXON CRUCIBLE Co., Jersey City, N. J., has recently brought out a graphite evaporator plate which is recommended as a substitute for the ordinary laboratory sand bath.

EDW. R. LADEW Co., INC., of New York City, tanner and leather belt manufacturer, has closed its sales office at Charlotte, N. C., and transferred its Southern headquarters to 95 South Forsyth St., Atlanta, Ga. An ample stock of belting and leather specialties will be carried, with the usual facilities for special work and engineering service.

WESTERN FELT WORKS announces the completion and equipment of its new buildings at 4031 Ogden Ave., Chicago, Ill.

The metallic arsenic plant at the HOSKINS PROCESS DEVELOPMENT Co., Chicago, was partly destroyed by fire on Wednesday, Jan. 11. The property was covered by insurance and is being rebuilt.

CHAIN BELT Co., Milwaukee, Wis., announces that George J. Blanton, who for the past four years has been connected with the engineering sales department, has been made New York district manager. Before joining the company in 1917 Mr. Blanton was associated with the General Electric Co. for eight years, three years of which were spent in Schenectady, N. Y., and five in the Milwaukee office.

CONVEYORS CORP. OF AMERICA announces that E. D. Kellogg has recently been appointed New Jersey representative in the northern half of the state. His headquarters will be at the Eastern office, New York City. This company also announces that S. D. Inman has been placed in charge of the engineering and design of its American Trolley Carrier, monorail conveying equipment for handling coal, ashes, sand, gravel and like bulky materials from railway car to pile, bin or bunker. Announcement is also made that the Power Equipment Co., 131 State St., Boston, has been appointed as New England representative for the sale of its American Trolley Carrier, monorail equipment for handling coal, ashes, sand, gravel and other loose bulky materials. Colwell & McMullin, 79 Milk St., Boston, are the New England representatives for its American Steam Ash Conveyor.

C. H. WHEELER MFG. Co., Philadelphia, Pa., has opened a branch sales office in the Leader-News Bldg., Cleveland, O., with W. K. Eicher in charge.

HAZARD ADVERTISING CORP. announces its removal to more spacious offices at 7 East 42nd St., New York City, which was made necessary because of the steady increase in the volume of the company's business.

COLORADO FELDSPAR, FLINT & MICA Co., Denver, Col., is planning to establish a crushing and grinding mill at Golden, Col.

AMERICAN WRITING PAPER Co. announced a new scale of prices on Feb. 1. In the list price reductions up to 20 per cent are announced. The average figure, however, is about 15 per cent below January prices. The lines affected by the reduction include practically all papers made by the company except certain specialties.

N. B. PAYNE & Co., New York, dealers in electric cranes and hoists, have extended their lines of material handling machinery to include the portable conveyors of the A. C. Warner Co., Philadelphia; Chicago Automatic Coal Elevators and McKinney-Harrington Package Pilers and Car Loaders. Edmund Otto is now connected in this branch of their business.

THE QUIGLEY FURNACE SPECIALTIES Co., INC., announces that owing to the general development of its business, it has disposed of the metals department. The General Alloys Co., under the management of H. H. Harris, formerly in charge of the metals department, will continue with the sales of Q-alloys. The General Alloys Co. can be reached at either 122 South Michigan Ave., Chicago, Ill., or 26 Cortlandt St., New York City.

New Publications

BOOKS

THE CHEMISTS' YEAR BOOK, 1920. Edited by F. W. Atack, assisted by L. Whin-yates. 5th ed., 1,136 pp. in two volumes. New York: Longmans, Green & Co., 1920. Price, \$7 net.

Since 1915 these volumes have been issued annually in a form resembling the German Chemiker Kalendar. From year to year revisions have been made and new material has been added. In the present edition the 180-page section on "Physico-Chemical Constants" has been completely revised by Dr. G. Barr of the British National Physical Laboratory. As a reference book for general data and analytical methods it will be found convenient and comprehensive. Both editorial and mechanical make-up merit special commendation.

A DICTIONARY OF CHEMICAL TERMS. By James F. Couch, chemist, Bureau of Animal Industry, Department of Agriculture. Pp. 204. New York: D. Van Nostrand Co., 1920. Price, \$2.50.

With the rapid growth and increasing specialization of chemistry new terms are often introduced in one branch of the science which are unfamiliar to workers in other fields. The chemist who tries to keep out of the rut by so planning his reading as to cover a broad field outside of his own specialty is often confronted with a new term or with a puzzling use of a common one. For the purpose of settling just such questions as those which have been suggested above Mr. Couch has unified the complex and scattered terminology of pure and applied chemistry, and presented the material in a form which lies somewhere between that of a standard English dictionary and that of an encyclopædia. Terms from related sciences which are likely to be met with are also defined, so that the book furnishes an excellent aid to study or reading any branch of chemistry or chemical engineering.

FROM NEWTON TO EINSTEIN. By Benjamin Harrow, Ph.D. Pp. 74. New York: D. Van Nostrand Co., 1920. Price, \$1.

This little book presents in a very readable manner a summary of the changes which have taken place in our conception of the universe from Newton's time to the recent much-heralded verification of Einstein's theories. While entirely popular in style this book might serve as an introduction to a phase of physical chemistry, which is increasing in importance.

THE ENGINEERING INDEX, 1919. Pp. 528. New York: The American Society of Mechanical Engineers, 1920. Price, \$4.

Covering as it does articles appearing in over 650 engineering and related publications this volume should be in the hands of all those who refer to the engineering literature. In securing the 12,000 items in this index the engineering staff reviewed approximately 1,100 periodicals, reports and other publications (in ten different languages) received regularly during the year by the Engineering Societies Library, New York.

CRAIN'S MARKET DATA BOOK AND DIRECTORY OF CLASS, TRADE AND TECHNICAL PUBLICATIONS. Chicago: G. D. Crain, Jr., 417 S. Dearborn St., 1921. Price, \$5.

This book has been compiled primarily as a reference book for advertisers. The general field for advertising is divided into related groups or industries. For each of these a short summary is given, covering statistics as to size and importance, manufacturing operations involved (if an industry) and a review of materials and equipment required. This is followed by a list of publications serving this particular group, including circulation, type page, page rates and other matter of interest to advertisers. The industries treated include, among others: Brick and clay products; cement, lime, sand, gravel and other quarry products; chemical industries; gas; iron and steel, metal working; meat packing and byproducts; fertilizers; petroleum; paint and varnish; glass; paper; leather; sugar; rubber.

EXPORTER'S GAZETTEER OF FOREIGN MARKETS 1920-21. Compiled and edited by Lloyd R. Morris. Pp. 789, maps and tables. New York: American Exporter, 1920. Price, \$10.

A vast quantity of up-to-date information on foreign markets has been gathered from scattered primary sources and arranged by countries under the main geographical divisions. For each country the book gives such data as: Area and population; commerce, statistics on industries and production; rivers, post offices, telegraphs, telephones and railroads; money, weights and measures; language; local advertising media; shipping routes; consular represen-

tatives, customs tariff and regulations; cable rate; mail time, and similar matters. Maps of the principal countries are included. Foreign currencies and measurements have been converted into American equivalents.

BIBLIOTHECA CHEMICO-MATHEMATICÆ: Catalogs of works in many tongues on exact and applied science, with a subject index compiled and annotated by H. Z. and H. C. S. These two volumes have 127 plates, which contain 247 portraits and facsimiles. Published by Henry Sotheran and Co., 140 Strand, W. C. 2, London, England. Price £3 3s.

HUMAN ENGINEERING, by Richard H. Mulliner, has just been issued. It is published by Mulliner Bros., 445 South Warren St., Syracuse, N. Y.

LABORATORY EXERCISES IN GENERAL CHEMISTRY, by William Martin Blanchard. Second edition. Published by D. Van Nostrand Co., N. Y. Price \$1.25.

STANDARD TESTS FOR REAGENT CHEMICALS, by Benjamin L. Murray. Published by D. Van Nostrand Co., N. Y. Price \$3.

PAMPHLETS

NEW BUREAU OF STANDARDS PUBLICATIONS: Circular 32, Standards for Gas Service; Circular 99, Carbonization of Lubricating Oils; Scientific Paper 399, Metallographic Etching Reagents: I—for Copper, by Henry S. Rawdon and Marjorie G. Lorentz; Scientific Paper 402, Use of Ammonium Persulphate for Revealing the Macrostructure of Iron and Steel, by Henry S. Rawdon; Scientific Paper 404, Magnetic Reluctivity Relationship as Related to Certain Structures of a Euctetoid-Carbon Steel, by C. Nusbaum, W. L. Cheney and H. Scott; Tech. Paper 173, Tests of Bond Resistance Between Concrete and Steel, by W. A. Slater, F. E. Richart and G. G. Scofield; Tech. Paper 178, Steel Rails From Sink-Head and Ordinary Rail Ingots, by George K. Burgess; Tech. Paper 179, Electric-Arc Welding of Steel: I—Properties of the Arc-Fused Metal, by Henry S. Rawdon, Edward C. Groesbeck and Louis Jordan; Tech. Paper 180, Causes and Prevention of the Formation of Non-condensable Gases in Ammonia Absorption Refrigeration Machines, by E. C. McKelvy and Aaron Isaacs.

NEW BUREAU OF MINES PUBLICATIONS: Petroleum Refineries in the United States, Tenth Annual Report of the Director of the Bureau of Mines to the Secretary of the Interior for the Fiscal Year Ended June 30, 1920; Bull. 117, Structure in Paleozoic Bituminous Coals, by Reinhardt Thiessen; Bull. 189, Bibliography of Petroleum and Allied Substances in 1918, by E. H. Burroughs; Bull. 191, Quality of Gasoline Marketed in the United States, by H. H. Hills and E. W. Dean; Tech. Paper 251, Ventilation in Metal Mines, a Preliminary Report, by Daniel Harrington; Tech. Paper 255, Chlorination of Natural Gas, by C. W. Jones, V. C. Allison and M. H. Meighan; Tech. Paper 264, Storage Battery Locomotives, by L. C. Ilsley and H. B. Brunot; Tech. Paper 271, State Mining Laws on the Use of Electricity in and About Coal Mines, by L. C. Ilsley.

ANNUAL REPORT OF THE DIRECTOR OF BUREAU OF FOREIGN AND DOMESTIC COMMERCE to the Secretary of Commerce for the Fiscal Year Ended June 30, 1920.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: "World Atlas of Commercial Geology" Part I, Distribution of Mineral Production; I: 7, Secondary Metals in 1919, by J. P. Dunlop (Mineral Resources of the U. S., 1919, Part I), published Jan. 31, 1921; I: 8, Chromite in 1919, by J. S. Diller (Mineral Resources of the U. S., 1919, Part I), published Feb. 4, 1921; I: 28, Copper in 1918, by B. S. Butler (Mineral Resources of the U. S., 1918, Part I), published Sept. 28, 1920; I: 29, Lead in 1918, by C. E. Siebenthal (Mineral Resources of the U. S., 1918, Part I), published Jan. 6, 1921; II: 5, Sodium Compounds in 1919, by Roger C. Wells (Mineral Resources of the U. S., 1919, Part II), published Nov. 16, 1920; II: 6, Potash in 1919, by W. B. Hicks and M. R. Nourse (Mineral Resources of the U. S., 1919, Part II), published Dec. 8, 1920; II: 7, Strontium in 1919, by George W. Stose (Mineral Resources of the U. S., 1919, Part II), published Dec. 9, 1920; II: 8, Gypsum in 1919, by Ralph W. Stone (Mineral Resources of the U. S., 1919, Part II), published Dec. 28, 1920; II: 9, Mineral Waters in 1919, by Arthur J. Ellis (Mineral Resources of the U. S., 1919, Part II), published Jan. 21, 1921; II: 10, Sand and Gravel in 1919, by R. W. Stone (Mineral Resources of the United States, 1919, Part II), published Jan. 5, 1921; II: 12, Foreign Graphite in 1919, by Arthur H. Redfield (Mineral Resources of the U. S., 1919, Part II), published Feb. 5, 1921.

IMPERIAL MINERAL RESOURCES BUREAU has issued pamphlets on "Asbestos" and "Bismuth."

THE EXTRACTION OF POTASH FROM LOW-GRADE ALUNITE FROM MARYSVALE DISTRICT, UTAH, by Thomas Varley and W. Spencer Reid. Bull. 13 published by the Utah Engineering Station, Department of Metallurgical Research.

FOURTH ANNUAL REPORT of the United States Council of National Defense, for the fiscal year ended June 30, 1920.

DEPARTMENT OF LABOR AND INDUSTRY has issued a bulletin on "What Pennsylvania Is Doing for Safety and Safety Codes," by Dr. Clifford B. Connelley, and "Report of the Activities of the Industrial Board."

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters will be at the Hotel Rochester.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon April 26 at Rochester, N. Y., for luncheon.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NATIONAL PETROLEUM CONGRESS will meet at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

REFRACTORIES MANUFACTURING ASSOCIATION will hold a meeting at the Hotel Pennsylvania, New York City, March 17 to 19.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP & PAPER INDUSTRY will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, N. Y., April 11 to 14.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

A Chance

To Try Again

THE Army appropriation bill, including among other things money for the Chemical Warfare Service, failed of enactment because it was pocket-vetoed by the President at the close of the last Congress. In many respects this is an unfortunate thing, as it leaves the new Congress with one added burden—namely, the provision for routine affairs of the Army for the next fiscal year. However, the cloud has a silver lining which is not hard to see, for it gives all of us another opportunity to boost the cause of chemical warfare again and with some hope that more adequate provision will be made for this branch of the Army.

Chemical industry is in many ways intensely interested in chemical warfare. A new aspect of this interest has recently become more conspicuous than ever before in the numerous claims against the Government for the after-effects alleged by those who have been gassed. There are nearly a million claims against the Government now pending in the War Risk Insurance offices. Nearly a quarter of these allege serious after-effects from gas. The intangible nature and the rather novel symptoms involved make it particularly difficult to settle these claims generously yet justly. The importance of this to chemical industry is obvious, for if the Government begins making adjustments for effects of gas every industrial establishment handling chlorine, phosgene, chlorpicrin and other toxic commodities of modern organic chemical activity will be confronted by unfounded claims for damage especially in states where industrial commissions look after workmen's compensation legislation. Chemical industries will, of course, not wish to dodge any right and proper responsibility in these matters, but at the same time it cannot safeguard itself too carefully against precedent that may be established by unreasonable generosity of the Government. One way to do this is to insure proper funds for study of these problems by C. W. S.

On many scores chemical industry and professional men generally will want to see all of the research and development work of chemical warfare properly advanced during the coming year. The only way to insure this is to see that Chemical Warfare Service gets the needed appropriations. That service originally asked for only about 2 per cent of the total sum which Congress proposes to grant for Army maintenance and operation. Yet this service is vital to every branch of the Army and without co-operation of this service every other branch is potentially useless against an enemy well prepared for chemical warfare. It is none too soon for all of us to emphasize these points to our representatives in Congress. In redrafting the Army bill for the new Congress at least double the amount

provided by the bill passed in the last Congress is essential. C. W. S. asked for eight and one-half million dollars. The Secretary of War cut this to four and one-half million before submitting the estimates to Congress, and Congress pared still further to one and one-half million. On this last basis the service can barely keep from slipping backward in mechanical plant and can do but a fraction of the needed research. It can make practically no masks at all. This would be a shameful condition. With \$3,000,000 the engineering facilities of the service can be maintained, a small amount of research and development work can be continued with a skeleton organization and a reserve supply of masks of each of the newer types needed can be made to replace obsolete forms now in hand. Surely that is the least which we can demand of the service during the coming year.

Research Opportunities of the South

DR. RAYMOND F. BACON, Director of the Mellon Institute of Industrial Research of the University of Pittsburgh, delivered a convincingly forceful address on "The Strengthening of Industries by Research and Experimental Engineering Work" at Macon, Ga., on March 15, before the leading representatives of Georgia's industries, at a meeting called to establish an industrial experiment station to be connected with the Georgia School of Technology of Atlanta. The convention was the sequel to the trip of inspection made last November by a party of Georgian manufacturers, accompanied by Governor DORSEY and Dr. K. G. MATHESON, president of Georgia Tech, who visited the important industrial centers of the North, and, while in Pittsburgh, familiarized themselves with the system of industrial research in successful operation at the Mellon Institute. It is reported that the Macon meeting was the largest gathering of industrial leaders ever held in the South, and it is understood that plans have been formulated to interest all lines of manufacturing in the project and to raise funds for the proposed industrial research establishment at Atlanta, to serve Georgia and that section of the South. The chambers of commerce and other civic organizations throughout the state are enthused and have indorsed the idea without exception, and the supporters of the plan have reason to believe that there soon will be a "Mellon Institute" in the Gate City of the South.

Dr. BACON's discourse was impressive in indicating the accomplishments of properly planned, systematically executed industrial research. He related the rôle played by scientific investigation in the development of the petroleum, cotton oil, sulphur, hydrometallurgical, and iron and steel industries; and he pointed to naphtho-py-
rolysis, hydrogenation and flotation as three of the

greatest results of industrial research. It was brought out by Dr. BACON that approximately \$25,000,000 is being spent annually by our industrialists in the conduct of laboratory chemical research, that probably an equivalent sum is being expended for unit experimental plant and factory investigational work, that several of our largest corporations are investing as much money in research as they are laying out for advertising, and that about \$50,000,000 is being saved each year through the application to manufacturing of the findings of scientific inquiry. The sum of \$400,000 was spent last year in carrying on industrial research at the Mellon Institute, where there are now forty-eight distinct technosubjects under study and eighty-three expert research chemists at work thereon.

Dr. BACON made particular reference to the opportunities which exist in the South, and especially in Georgia, for using research in the upbuilding of industry, especially in connection with wood products, textiles and vegetable oils. The field of problems invites investigational exploration, and the Georgia School of Technology provides the port of embarkation for the expedition.

The Chemistry Of Olfactics

A CORRESPONDENT of the London *Daily Mail* lately contributed a note on some curiosities of smelling. He found three or four hens pecking over a rubbish heap on which some calcium carbide had lately been thrown, and while the place reeked of acetylene the hens did not seem to mind it. He observes that the sense of smell of birds is generally slight, that their olfactory bulbs are very small, and that in some, such as the frigate bird, the nostrils are obliterated. On the other hand, regarding man, he declares that the half-savage Ainu of north Japan can track game like a dog, by the nose alone. JAMES MITCHELL, the English blind deaf-mute, recognized his friends when they came into a room, simply by their smell. Dean BUCKLAND, the geologist, when riding once with some friends and the party lost their way and were overtaken by night, alighted from his horse, picked up a handful of earth, smelled it, and at once declared they were near Uxbridge. He knew the geology of the land and the smell of the soil.

Of dogs the *Mail* correspondent says that the opinion prevails that they are better able to follow scent on a dull, damp day than in the bright sunlight when dry air prevails, but that even this cannot be put down as a hard and fast rule. Scent may be good in the morning and bad in the afternoon, and *vice versa*, and hounds that are at fault in the morning may run hard later in the day. The powers of scent of such dogs as setters and retrievers vary greatly at different times. On a September afternoon, he says, a famous hunter shot and wounded no fewer than ten partridges, which were running in that condition, although his retriever could not find any of them. He then waited until the cool of the evening, brought her back to the same spot, and within ten minutes she had tracked down every one of the birds.

"Why," the correspondent asks, "are cats so strangely fond of valerian? Why are stoats and weasels attracted by the oil of musk?" The answer is probably entangled in sex phenomena, while his declaration that a vixen with her cubs hardly leaves any

scent behind her has at least the odor of a kind of provision of nature. When he asks, "Why are rats so keen on aniseed and rhodium?" we acknowledge ourselves beaten, more particularly in regard to rhodium. If they have such a passion for rhodium they can hardly be indifferent to platinum, and an ex-president of the Electrochemical Society suggests a real use for rats in this connection. He proposes that they be used in prospecting for platinum and as an aid to detectives in locating stolen crucibles. We wonder what the London writer wrote that the printer mistook for rhodium!

But where is the chemistry of all these curious reactions? What is scent, anyway? What happens when we smell? What are the carriers of odor? What reactions take place on the sensitive plates in the nostrils where the nerve termini are embedded in lipoid substance? What's the use in talking big about chemistry when nobody can tell us of the process of smelling? How many atoms must a molecule contain to have the olfactory quality? And how many carbon atoms mark the limit of this quality? The cellulose molecule seems to have no odor. Has it too many carbon atoms to produce the phenomenon? If we only knew how many carbon atoms the cellulose molecule contains we should know a lot more than we do now. Dr. THOMAS H. DURRANS, an English investigator, has expressed the opinion that odor is due to unsatisfied bonds within the molecule. That may be true, but the rest of us do not seem to know enough either to confirm or to deny it. The subject is unstudied, and it needs attention.

The Ways and Habits of Micro-organisms

IT WAS during convocation week at Chicago in December last that Dr. SIMON FLEXNER made his famous presidential address at the meeting of the American Association for the Advancement of Science. He called it "Twenty-five Years of Bacteriology: a Fragment of Medical Research," and we commend it to our readers as a model of scientific literature. It was published in the December 31, 1920, issue of *Science*. He began with the meeting of the German Society of Naturalists and Physicians in 1895, when the announcement was made of the conquest of diphtheria by an antitoxin. Establishing that as a landmark, he proceeded to lead up to it by a historical introduction, not for the purpose of giving dates and mentioning names, but to give, which he succeeded in doing, a clear picture of the state of the art at the time. Then followed a discussion on the high lights of what has been done since. It is a very illuminating essay, with the theory and application of science made remarkably clear.

We have published articles on the uses of micro-organisms in industrial chemistry, but we want more. We need more industrial biochemistry. The fermentation of ethyl alcohol from sugar is studied and available, but we do not know enough about the production of glycerol by a similar process or of the zymotic production of amyl alcohol from protein substances—e.g., from the germs of grains. We have hardly lifted the cover of this great treasure store of industry as yet. Elsewhere we have expressed the hope that some day the chemical factory will be as greatly desired in a neighborhood as a public library or a school. That will be when we work more delicately than we do now;

when we let the microbes do our work for us. They require great cleanliness to keep the strains pure, but when the conditions are favorable they scorn union hours or minimum wages or overtime, and they work while we sleep. The time is ripe for some FLEXNER of industrial chemistry to give us such a paper on biochemical technology or chemical biotechnology, whichever you please. True, FLEXNERS are scarce, but we are not keen about names. It is the work we are after.

Hours of Service

In the Steel Industry

THE iron and steel industry expects the United States Steel Corporation to present within a few weeks a solution of the difficult problem of the hours of service in the industry. Many years ago it became the custom in some departments to have men on duty twelve hours a day seven times in the week. Fortnightly, when the day and night shifts changed places, there was a twenty-four-hour spell. The practice was due partly to competition among manufacturers and partly to the willingness of the labor, chiefly foreign born, to work very long hours. In the Steel Corporation's annual report for 1912 it was stated that the corporation was observing the six-day week. This was accomplished by having a twenty-four-hour interval each week in the production of ingots and by giving men at blast furnaces a day off in the week in rotation. Thus the twenty-four-hour spell for a given man every fortnight was eliminated. The corporation's practice in this matter has not been universal, and at any rate the twelve-hour day has remained except at a few works.

Usually the problem has been considered as involving simply a choice between two twelve-hour shifts and three eight-hour shifts, since the machinery works continuously. Many of the men do not, but the precise time at which they may be required cannot always be predetermined, and it is requisite for full utilization of the plant equipment that the men who do not have to work continuously be subject to instant call. Many of the men prefer the long hours with the attendant pay in preference to a much shorter day with but a slight diminution in the daily earnings. The social workers recognize, as do others, the advantage to the country of shorter hours on duty and of more Americanization, but they have been disposed to place the whole task before the employers. The desire for a shorter day with opportunity in leisure hours for recreation and self-improvement, with the employee bearing a reasonable part of the expense, has not been inculcated in the minds of these workmen.

When the demand for pig iron and steel products is heavy, as in 1920 when buyers bid from three to five times the pre-war price for many classes of steel, a large curtailment in the supply would occur if the hours were shortened, because additional men could not be obtained. When, as at the present time, the iron and steel industry is faced with the necessity of producing cheaply and economically in order to make a market, without which there would be no employment at all, it is essential that the operation of production be efficient. Every man must do a fair day's work for a fair day's pay. The economics of the situation will not countenance any other condition. There is a horrible example in the case of the railroads, whose payrolls as recently constituted included about 1,950,000 persons. At five persons to a bread-winner that

meant 9.2 per cent of the population dependent on the railroad payrolls. Such a division of the sum total of the work of the people is impractical, and the iron and steel industry would be committing partial suicide, if use of such a term be permitted, if it adopted a system that did not provide a full day's work for each man on the payroll.

To leave all work to be done as it is done now and have three men per twenty-four hours instead of two men to perform the services is impractical on economic grounds, but hitherto the problem has been regarded as a mere choice between two shifts and three shifts. In view of the fact that a committee composed of presidents of subsidiary companies of the Steel Corporation has been hard at work on the subject it is a fair presumption that an elimination of the twelve-hour day is being sought by substitution of a system that will be much less inefficient on economic grounds than an eight-hour period of service, with general methods of operation unchanged. When no solution of the vexed problem has hitherto been proposed that seems economically sound, and when the Steel Corporation evidently finds the task so difficult, it is idle to speculate as to what will be the outcome of the present study, but from all the circumstances it seems fair to conclude that within a short time a system will be put into actual operation that will eliminate unduly long hours of service and yet will provide that each man does a fair day's work, so that the country will not be devoting an undue amount of its total time to the production of pig iron and steel. It is now committing such an economic crime in the case of railroading and coal mining, and would be including a third in the case of the building trades if the unions in that line had their way. The country could not stand such a collection of crimes, its duty being to reduce, not increase, the number.

Science in the Public Service

THE National Research Council is contributing splendidly to the cause of chemistry and chemical industry by the exhibit which it is showing of the relation between chemistry and both peace-time and war-time industrial products. This exhibit, prepared largely by the Chemical Warfare Service, strikingly portrays the close relationship of explosives and material for chemical warfare to the peace-time products of the dye, pharmaceutical and other organic chemical industries. Taking coal, salt, sulphur and air, which remind us of the alchemists' elements, this exhibit shows the diversity of product which modern chemical industry furnishes for the comfort and protection of mankind. It makes one believe that the ancient alchemist was nearer the truth than most histories of chemistry would lead us to believe when he considered air, water, earth and fire as the elements. Certainly the number of truly basic substances of industry is fewer than we commonly believe, and the interrelation of industry is much closer than modern commercial practice would show.

It is to be hoped that the purpose of this exhibit will be generously realized in the education of legislators, professional men and the general public. Particularly we should like to see a keener appreciation of the great importance both in peace and in war times of that effort which is basic to the Chemical Warfare Service.

Readers' Views and Comments

Fundamentals Essential to Soundness of Steel Rails

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Jan. 26, 1921, you published a communication from George F. Comstock, metallurgical engineer of the Titanium Alloy Manufacturing Co., headed "Relationship Between Segregation and Rail Failures." On the face of it Mr. Comstock has made out a very good argument for the titanium-treated rail, but so much more data as to the service conditions of the various tests quoted are necessary before an engineer or metallurgist could draw intelligent conclusions that the whole argument loses much force and as it stands is possibly misleading.

Mr. Comstock also makes one statement of fact that I must take direct exception to. I quote: "Theoretically there is no question that the sink-head process is effective in eliminating pipe in ingots, but piping can be controlled also by care in ordinary methods of ingot manufacture. For instance, in a recent rolling of standard titanium-treated rails, the top discard averaged 8.3 per cent from the ingot, and by keeping the silicon content of the steel below 0.10 and pouring slowly, the piped rails were kept down to 4.5 per cent as determined by the nick-and-break test on every ingot. No special molds or hot-tops were used."

Does he mean by "sink-head" process the putting of a sink-head on an ordinary big-end-down ingot? This is admittedly valueless, as the sink-head only hides the secondary pipe or shrinkage, which at times occurs down in the bottom 20 per cent of the ingot. The only true value of a sink-head in producing physically sound steel is when it is used in conjunction with a big-end-up or inverted ingot mold. This has been clearly explained by Dr. H. M. Howe and so many others that it need not be reopened to argument. I feel that Mr. Comstock committed a great error in referring to sink-head ingots without stating whether the mold was big end up or big end down, thus making a statement that is at least indefinite and may readily damage the cause of physically sound steel.

As a matter of fact, the big-end-up ingot with the refractory sink-head has been in use even in this country on the highest quality sound steel products for twenty years or more, and its use is constantly growing until last year over a million tons of ingots were cast this way. This can therefore hardly be considered "theoretical."

Mr. Comstock speaks of eliminating pipe. Pipe is the volumetric shrinkage of steel when going from the molten to the solid, and of course cannot be prevented. It can only be so controlled that it will appear in a small portion by weight of the upper end of the ingot. It can only be eliminated by cropping the piped portion of the ingot.

I quote further from Mr. Comstock: "But piping can be controlled also by care in ordinary methods of manufacture."

In my understanding the only things that the steel maker can do to control pipe in ordinary methods of manufacture, using a standard big-end-down ingot, are:

First: To only partly deoxidize or not to deoxidize the steel, thus forming blowholes all through the ingot instead of pipes. Unless the object is to produce a coarse steel sponge, this is inadmissible.

Second: To roll the ingot before solidification has completely taken place, according to the plan suggested by Talbot. This produces so-called "cokey," gray or soft centers, a condition prohibited in all ordnance and high quality steel, and now prevented in the latest rail specifications. (A.R.E.A. 1920, Par. 31.)

Note B of these specifications says: "The steel must be well deoxidized and the waste products eliminated before teeming," thus definitely prohibiting the use of a steel that will form blowholes. It is only by the doing of one or the other, possibly both, of these indefensible things that ingots could be produced in ordinary molds that would give a yield of 91.7 (8.3 per cent top crop) with only 4.5 per cent of the rails showing pipe on the nick-and-break test.

It is probable that in making these estimates of percentage of crop necessary to reach sound metal Mr. Comstock has fallen into the error that so many metallurgists and the writers of so many specifications also fall into—viz., that the visual examination of the fracture of a finished part is sufficient to detect physical flaws in the metal and insure soundness.

An examination of the fracture in a nicked and broken rail does not reliably show up a cokey center, although the longitudinal fracture of the bloom from which the rail was rolled does. Hence this is where the inspection for physical soundness should be made, and it can be made at this point without interfering in any way with manufacture or adding to cost. When this is done, inspection will catch the deeply hidden flaws which at present slip by on the inspection only of the finished product and later cause such dangerous breaks as transverse fissures, shattered zones and split rail heads.

The fundamentals essential to the soundness of steel rails are:

First: That the bath of metal be thoroughly deoxidized before teeming, so that no chemical reaction can taken place during solidification.

Second: That the metal be cast in an ingot mold whose inside dimensions are enough greater at the top than at the bottom to prevent internal bridging.

Third: That the ingot after teeming be kept in substantially a vertical position, either in mold or soaking pit, until solidification is complete.

Fourth: That a refractory sink-head be used on all ingots.

Mr. Comstock holds that titanium promotes soundness in that it is the best of all known deoxidizers, and that is of course his argument in the letter in question, for he says: "We have found, moreover, that no titanium-treated rail is ever segregated if the treatment has been properly made, so that there is a small residual content of titanium." This implies the complete deoxidation of the steel, as otherwise there could be no residual titanium. An important question from a commercial stand-

point which might be discussed in this connection is this:

Can steel, such as rail steel, be completely deoxidized with titanium alone when the silicon is kept down to 0.10 per cent, and what is the cost per ton of doing this? I am asking this because as I mix with steel makers I find that they are only using titanium as a partial deoxidizer in such products as sheet bar and plates, possibly others of the same class, and its effect thus used is only to deepen the location of the blowholes which form in all open steel ingots. This only hides the flaws more deeply in the steel and makes them harder for the buyer of the steel to find, but the user ultimately does find them when the part breaks in service or fails by corrosion. In my opinion this is a false and uneconomical use of titanium, though it may be commercially profitable today. Its true use, if it is to be of any permanent value in the steel industry, is either as a deoxidizer or alloy, and not as a "dope."

Segregation is always present in all ingots. It is an inherent condition in all steel which forms by selective freezing, and hence Mr. Comstock's statement that no properly titanium-treated rails ever show segregation is of course not literally true. The thing which should be said of titanium is that it retards and minimizes segregation, and this is also true of many other deoxidizers. For this reason, and also because a thoroughly deoxidized bath prevents blowholes and concentrates the entire volumetric shrinkage of the steel in one pipe cavity, deoxidation is the first fundamental essential to soundness. Mr. Comstock ought to agree with me here. Use of a big-end-up mold with a deoxidized bath of metal automatically locates all pipe and much unavoidable segregation in the upper part of the ingot, where it can be cropped and discarded, and hence the big-end-up mold is the second essential to soundness. Use of the sink-head with the first two makes it possible to crop all pipe and dangerous segregation with less than 10 per cent of the ingot weight, and therefore it is a commercial essential. Holding the ingot vertical until solid prevents cokey centers and the extremely dangerous flaws that are attendant thereto, and is therefore essential to soundness. It is my opinion that cokey centers cause more breaks in rails than all other defects put together, chemical segregation included.

Mr. Editor, I wish to call attention to your editorial of Nov. 17, 1920, headed "Why Not Turn the Mold Over?" and most positively state in support of the ideas contained there that as long as rail makers and rail users continue to compromise with the "big-end-down mold fetish," as they are still doing today, they will continue to get rails full of dangerous hidden flaws. Furthermore, if they will turn the mold over and employ the three other fundamentals essential to soundness, they can get uniformly sound rails and at no appreciably greater cost.

GEORGE A. DORNIN,

Gathmann Engineering Co.

Consulting Engineer.

Mr. Comstock's Reply

To the Editor of Chemical & Metallurgical Engineering

SIR:—In regard to the service results on titanium-treated rail, it should be understood that these were not from special tests conducted by the Titanium Alloy Manufacturing Co., with all conditions carefully controlled. They were purchased by the railroads at a

slight increase in cost above that for ordinary rails, and naturally were placed in track where the service conditions were severe so that this increase in cost might be repaid in service. If Mr. Dornin or any other interested person will take the trouble to refer to the published records of the American Railway Engineering Association he will readily see that the tonnages involved are large enough to make the various results thoroughly practical and representative of actual track conditions. It is hard to see any justification for the charge that my argument was possibly misleading, since the results originated with the railroads themselves, which would naturally be most interested in placing the titanium-treated rails where they would be exposed to service conditions more severe than the average.

Most of Mr. Dornin's criticisms seem to be the result of the brevity of my former letter, but it should be remembered that that was just a letter and not an exhaustive paper on the subject. When I mentioned the sink-head process, I of course meant this process properly used; it was not necessary to state this in detail, as my letter was in reference to Dr. Burgess' articles, where all these details were mentioned. I reiterate that piping can certainly be controlled by the way the steel is poured into the molds. In the rolling mentioned (with a top discard averaging 8.3 per cent) the ingots were completely deoxidized and not rolled with liquid centers, yet only 4.5 per cent of the rails showed pipe on the nick-and-break test. The inspection for pipe was, of course, made in the usual, standard manner specified for the nick-and-break test, and by the regular inspectors accustomed to this test. There is no question that pipe can be accurately determined in this way. There is absolutely no reason why a soft center in a rail should be confused with unsoundness, and there is no published evidence known to me that a soft center ever did a rail any harm or caused a transverse fissure, a shattered zone or a split head. I have examined quite a number of failed rails, and have carefully studied all other reports of such examinations that I could find, and have never found any case of trouble caused by a soft center. Most failed rails, on the other hand, are segregated and have a hard center.

In reply to Mr. Dornin's question about deoxidizing rail steel, our experience with thousands of tons of this steel shows that it can be deoxidized completely by the usual manganese addition, silicon in an amount giving from 0.06 to 0.10 per cent in the final steel, and 13 lb. of ferrocen-titanium per ton. The cost of ferrocen-titanium is 10c. per lb., making the actual cost of the treatment \$1.30 per ton, in rail steel. In soft steel, such as for sheet-bar and plates, this is probably not true. In this class of material experience shows that effervescing steel gives the best results, so that titanium is generally used in it as a partial deoxidizer and cleanser. This use is giving improved results in many mills, which is a stronger argument for using it than mere opinion. In most of this steel a good clean surface is the important point, and it has yet to be shown that a good surface implies hidden defects causing breakage or corrosion in service.

The quotation from my letter about "no properly titanium-treated rails ever showing segregation" is another instance where a phrase isolated from its context may have an unintended meaning. In connection with the table and paragraph where this statement occurred

in my letter, it should be apparent that by "segregated rail" I meant one with over 12 per cent segregation of carbon between the upper corner of the head and the junction of head and web.

I have always been a supporter of the Gathmann mold, and believe that its use will produce better ingots with less waste than the ordinary molds produce; but it is the deoxidation of the steel, and not the type of mold used, that controls or minimizes segregation, which when uncontrolled is the cause of more rail failures than any other defect.

GEORGE F. COMSTOCK.

Metallurgical Engineer,
Titanium Alloy Manufacturing Co.

Easy Money From Peat

To the Editor of Chemical & Metallurgical Engineering

SIR:—I happen, unfortunately, to be the "Charlie" you mention so many times in your story on "Easy Money From Peat" in your issue of Feb. 2, and can say that every word in it is the truth. If your gentleman would have stayed or waited until called back by the Professor after being ordered out of the basement and witnessed the second demonstration quickly staged by the inventor you would have had a complete story and not part of one. What I saw accidentally, as I could not very well be ordered out with the others, though it was against the Professor's wishes to have me stay, I could not very well write, as I would not like to sign my name to it, as it might be going too far. I resigned that evening as secretary and treasurer of the company, so you might imagine what I saw was not very pleasant. George and myself happen to be too honest young men full of ambition; and as the Professor promised us a lot and we having no knowledge of chemistry, we took a chance, thinking the Professor and his process were straight.

EDITOR'S NOTE. For obvious reasons the name of our correspondent is omitted. The communication is valuable, however, in support of the statements made in our article. It has been brought to our attention that some of our readers believed the article to be a figment of the imagination, but we wish to assure them that it was a statement of fact.

Research, a Capital Investment or an Operating Expense?

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with a great deal of interest and approval what is written under the caption "Research, a Capital Investment or an Operating Expense?" in your issue of Feb. 2. On some of my advertising matter I have carried for a number of years the following: "Money expended for professional advice is capital invested, and should be so entered on the books." Credit for this eminently safe and sane dictum is given to the *India Rubber World*.

It seems to me that a great many managers of industrial enterprises fall into two very serious economic errors. The first is that of considering an expenditure as synonymous with expense, while the second is that of regarding a reduction of expenditures as necessarily an economy. England's great Prime Minister Disraeli years ago said: "True economy does not consist in a reckless reduction of expenditures; on the contrary, such a course almost inevitably results in increased expense—there can be no economy where there is no efficiency."

If there ever was a time when it would be profitable

to display a wise liberality in expenditures to promote industrial efficiency, to increase the buying power of money by a careful inspection of all material bought, and, above all, by a rigid supervision showing how material is used, this is the time above all other times. In the case of fuel, for instance, selling as it does at such enormously high prices, what economies might be effected if its use were under the continuous supervision of competent fuel engineers!

It appears, though, that the editor of *Drugs, Oils and Paints* was about right when he said many years back: "It would seem that the average American manufacturer prefers to go to his ruin on his own responsibility rather than to go to success by the aid of outside help." Going still further back, one Lucius Æmilius Paulus said in 165 B.C.: "I would call that man more proud than wise who attempted to do everything by his own unaided judgment."

Since the days of this old Roman men have probably grown more proud. Have they, in matters of industrial efficiency, grown very much wiser?

Baltimore, Md.

WILLIAM N. BERKELEY.

The Hargreaves-Bird Electrolytic Cell

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read J. B. C. Kershaw's description of the Hargreaves-Bird cell, as appearing in your issue of Jan. 12, 1921, with interest, as certain of the information contained therein is new to me. But I would particularly refer to his remark that "this company has been operating under the war conditions of inflated prices." I have always taken interest in so-called derelict companies and processes, and I have been fortunate enough in being able to show, on more than one occasion, that such companies and processes have been wrongly described. A very large number of experts considered the Hargreaves-Bird cell was a failure and pointed to the misfortunes of the Electrolytic Alkali Co., Ltd., as a proof of their theory, and it seems to have annoyed them considerably to find that their views have been proved incorrect. Some of them, unfortunately, are not generous or broadminded enough even now to admit that they were wrong.

In September, 1916, the Ministry of Munitions decided, after going into details of cost, that a fair price for bleaching powder made under a certain process was £10 per ton, but because our process was more efficient the price they would pay us would be £7 10s. per ton. The Ministry of Munitions did not alter that price until January, 1918. During this period it is obvious that the cost of labor, raw material, etc., increased to a considerable extent, and it was only by continuous improvement that we were able to maintain the margin of profit. Had we been able to sell our bleaching powder on the open market we should have got, during the latter part of this period, anything from £25 to £40 per ton. Further, we were pleased to assist in making certain poison gases, and we did this at net cost of labor and material, plus a small percentage, which percentage was very much below our standing charges. Obviously, therefore, there was no profit for our organization under this head.

The above will show that the prices we got for our products, to say the least of it, were not inflated prices.

Atoms and Metals

Summary Outline of Modern Views of the Ultimate Constitution of Matter — Nature of Forces Existing Between Atoms in Gas, Liquid and Crystalline or Amorphous Solid as Affecting the Commonly Measured Physical Properties of Metals

BY ZAY JEFFRIES AND R. S. ARCHER

Research Bureau, Aluminum Company of America

DEVELOPMENT of metallographic science is evident in the direction of a thorough study of the constitution of matter. The microscope has revealed structures in metals unsuspected by the naked eye, and has made intelligible much of the behavior of metals which was formerly quite mysterious. The range of the microscope is limited, however. We know in many cases that structural changes are taking place on a scale so minute as to lie beyond the resolving power of the microscope and yet are producing revolutionary changes in the properties of the metal. Since the study of the structure of metals with the microscope has yielded results of such great practical value, we may expect that the extension of this study to those details of structure which lie beyond the resolving power of the microscope will result in a corresponding extension of our useful knowledge of metals.

In the complete analysis of structure we are concerned with the ultimate particles of matter—the electron, atom and molecule. It is not sufficient merely to recognize that such particles exist and that the atom is an extremely small particle of matter which is the unit of chemical combination. We must gain some appreciation of the actual sizes of these particles, of their properties, and their relations with one another. In this way a mental picture can be formed of the manner in which metals are built up and of the mechanism of the changes in structure and properties which affect their utility. The knowledge of the ultimate particles which is now available is not enough to make our pictures entirely complete and accurate, but it is enough to make them useful.

CONSTITUTION OF ATOMS

The electron has the smallest mass of any particle of which we have any knowledge. The word "electron" was first suggested in 1891 by Dr. G. Johnstone Stoney as a name for the natural unit of electricity, or a unit electrical charge (4.77×10^{-10} electrostatic units). It is now almost universally applied to certain very small particles which possess a definite mass and carry a single negative electric charge. It is quite possible that the mass of the particle is entirely of electrical origin, and that the unit electrical charge actually constitutes the particle. The mass of the electron is about $\frac{1}{1836}$ that of the lightest known atom—namely, the atom of hydrogen. Assuming that this mass is entirely of electrical origin, it can be calculated that the radius of the electron is about 2×10^{-13} cm. Experimental evidence shows that the size of the electron is actually of this order of magnitude, which is very small as compared with the diameter of an atom. Because of their negative charges, electrons are to be regarded as repelled by each other and attracted by positive electrical charges.

It is now considered quite certain that atoms are built up of negatively charged electrons grouped about positively charged nuclei.¹ The charge on the nucleus of an atom is exactly balanced by the negative electrons surrounding it, so that the atom as a whole is electrically neutral. Independent methods of experiment have estimated the exact number of electrons in the atoms of the various elements. If the elements are arranged in the order of increasing atomic weight and numbered consecutively from 1 to 92, with a few omissions, the numbers thus assigned are called the *atomic numbers* of the elements. According to this conception the atom of each element has a number of electrons equal to its atomic number; thus hydrogen has 1, helium 2, iron 26 electrons, etc. Fundamentally, different kinds of atoms owe their individuality to their positively charged nuclei; the charge on the nucleus evidently determines the number of electrons which will be held about it by electrostatic attraction. These electrons will naturally group themselves into some most stable arrangement which must be different for different numbers of electrons. Atoms of the various elements differ therefore in the character of their nuclei, and the number and arrangement of electrons.

ATOMIC MASS AND VOLUME

The mass of an atom is due almost entirely to its nucleus. A hydrogen atom contains only one electron, having a mass approximately only $\frac{1}{1836}$ that of the atom, while the atom of uranium, which contains 92 electrons, has a mass about 236 times that of the hydrogen atom. In the latter case the contribution of the negative electrons to the total mass is still more insignificant. The total mass of the atom increases with the charge on the positive nucleus, but not in a perfectly regular manner.

The actual mass of the hydrogen atom has been determined and has a value of 1.662×10^{-24} g.; its atomic weight is 1.008. If we imagine a hypothetical element with an atomic weight of unity, the mass of its atom would be 1.643×10^{-24} g. The actual mass of the atom of any chemical element is the product of its atomic weight by the mass of this hypothetical atom. For example, the mass of an iron atom = $55.84 \times 1.643 \times 10^{-24} = 9.174 \times 10^{-23}$ g.

The size of an electron is known to be very small as compared with the volume dominated by the atom of which it is a part.² The radius of the latter volume is probably of the order of 50,000 times the radius of the electron. It is believed that the heavy posi-

¹Langmuir and Lewis have recently developed a general hypothesis regarding the positions of electrons in atoms and molecules which promises to be very far reaching. For a clear exposition of this theory see "The Langmuir Postulates," by Ellwood Hendrick, *CHEM. & MET. ENG.*, vol. 21, p. 73, July 15, 1919.

²"The Electron," R. A. Milliken, Chicago University Press.

tively charged nucleus of the atom is still smaller than the electron. An atom consists, therefore, chiefly of empty space. It is possible to project one atom through another without striking the nucleus or any of the electrons in much the same way that a comet might shoot through our solar system, without striking the sun or any of the planets.

In view of the open nature of its structure, an atom cannot be said to possess a definite volume, in the sense of a space inclosed by a bounding surface, but in any given material we can determine the volume per atom, which we may for convenience call the volume of the atom, always recognizing that we mean merely the volume dominated by the atom, or its "sphere of influence." In this sense it is quite simple to calculate the volume of an atom from its mass and the density of the element. Taking iron again for an example, the density is 7.87 g. per c.c. The number of atoms in 1 c.c. is then

$\frac{7.87}{9.176 \times 10^{-23}}$; the reciprocal of this number is the volume per atom, and figures 1.166×10^{-23} c.c. This calculation depends of course on the value taken for the density of iron, which varies with the temperature, pressure, and arrangement of the atoms—i.e., physical form. Therefore the volume of an atom in this sense is not a constant property of the atom like its mass. A set of numbers representing the relative volumes occupied by atoms is obtained by dividing the atomic weights of the elements by their densities when in the solid state. Physically, the number thus obtained gives the volume in cubic centimeters of an atomic weight in grams (gram-atom) of the solid element, and is called the *atomic volume* of the element.

VISUALIZING THE SIZE OF ATOMS

It is difficult to imagine the size of such small objects as atoms. Tungsten, for example, which has a specific gravity of slightly over 19, requires about 100,000,000 atoms as they are normally spaced at room temperature to make a linear inch. A 1-in. cube of tungsten would, therefore, contain about 1,000,000,000,000,000,000,000,000 or (10^{24}) atoms.

We are in the habit of visualizing all objects in terms of things which we can see with the unaided eye—e. g., we make a map of as large an area as the continent of North America and reduce it to such an extent that we can see its general geographical characteristics on one page, or one map. On the other hand, we magnify objects too small to be seen with the unaided eye to such an extent that we can see the photograph or other physical likeness with the unaided eye. We cannot visualize the size of an atom, owing to its smallness, but we can gain some idea of the ratio between atomic dimensions and one of the smallest units which can be readily seen with the unaided eye—namely, 0.01 in. Let us suppose that instead of atoms we have spheres 0.01 in. in diameter. Let us further suppose that we make up a cube composed of 10^{24} of these spheres closely packed. This cube would be 1,000,000 in. on a side, or over 15 miles. Consequently, the diameter of a tungsten atom is to 1 in. as 0.01 in. is to 15 miles, and the space dominated by a tungsten atom is to 0.000001 cu.in. as 0.000001 cu.in. is to 225 cubic miles. This comparison may be equally difficult to comprehend, but it at least calls strikingly to our attention the very small dimensions of the atoms.

INTERATOMIC FORCES

Atoms exert upon each other both attractive and repulsive forces. Thus, metallic iron is an aggregate of crystals built up of atoms arranged in a definite manner, and any attempt to separate these atoms from each other, as by the application of a tensile load, is opposed by the cohesion of the metal, which results from the attraction of the atoms for each other. If a small tensile load such as 3,000 lb. per sq.in. is applied, the distances between atom centers in the direction of the load increase by a certain amount in accordance with the elastic modulus—in the case in point, 0.01 per cent. On removal of the load the atoms return to their original positions.

Similarly the atoms are moved closer together by hydrostatic pressure, resisting the pressure because of the repulsive forces between them. When the pressure is released these forces restore the atoms to their original positions.

Atoms of a solid are thus held in equilibrium positions by a balance of their forces of attraction and repulsion. On being forced closer together the repulsive forces increase more rapidly than the attractive forces and the resultant force is a repulsion which varies approximately as the displacement of the atoms from their equilibrium positions. When the atoms are pulled farther apart than their equilibrium positions, the resultant force is attractive and again is approximately proportional to the displacement of the atoms from their equilibrium positions.

At all temperatures above absolute zero the atoms of the solid elements are in a state of vibratory motion about their equilibrium positions. The frequency of vibration is on the order of 6×10^{12} cycles per second, and does not vary greatly with the temperature; the amplitude of vibration does increase with the temperature, however, thereby increasing the kinetic energy of the particles. In fact, *temperature* is a term used to indicate the mean kinetic energy of the particles of a body.

All of the common properties of a body change with the temperature except the mass. This must be due to the changing motion and energy of the atoms, since the specific properties of the atom itself do not appear to be affected by temperature. The property of radioactivity, for example, seems to be a characteristic property of certain atoms and does not vary with temperature. Similarly, the spectra of the elements exhibit an independence of temperature, again indicating constancy in the properties of the atom.

The phenomenon of crystallinity is evidence of a natural orderly arrangement of atoms. A crystal is made up of atoms held together by attractive forces which must necessarily be exerted in definite directions to give rise to the geometrical symmetry of the crystal. No element is known which does not occur in crystalline form, both in the pure state and in chemical combination with other elements. The X-ray spectrometer is constantly giving proof that many substances, once considered amorphous, are in reality crystalline and are built up of atoms arranged in definite and repeating patterns.³

This property of exerting force *directionally* is therefore a characteristic property of atoms, and because

³Important results derived during the last decade by X-ray analysis will be discussed in a later contribution on the structure of metals.

of the directional quality of the forces between atoms, the crystalline form is the normal form of matter in the solid state.

MOLECULES

Certain groups of atoms held together by atomic forces constitute molecules. Hydrogen, for example, consists of discrete particles, which we call molecules, each one made up of two hydrogen atoms. Hydrogen in the atomic state is an extremely active substance, combining with explosive violence with many elements, such as oxygen and chlorine. When the atoms of hydrogen unite with each other in pairs to form hydrogen molecules, the attractive forces about the atoms are largely satisfied. Molecular hydrogen is accordingly a very inert gas. Hydrogen molecules have little attraction for each other, as is shown by the very low boiling point of liquid hydrogen. It can be mixed with oxygen at ordinary temperatures without any reaction taking place. But when the mixture is heated some of the molecules are dissociated by the thermal impacts, and the atoms thus freed start the chemical reaction. The heat liberated continues the process of dissociation so that the reaction rapidly becomes complete.

Equal volumes of gases under similar conditions of temperature and pressure contain equal numbers of molecules (Avogadro's law). From this law the number of atoms to the molecule of a gas can be determined by measuring the density of the gas under definite conditions of temperature and pressure. Such measurements show that the molecules of the non-metallic elements in the gaseous form contain two or more atoms, with the exception of the inert gases of the helium group, which are monatomic. Atoms of the rare gases apparently do not exert sufficient attractive force to combine into molecules. Vapors of the metals also contain only one atom to the molecule.

Atoms of such elements as oxygen and chlorine exert upon each other definite attractive forces which cause them to unite in pairs to form fairly inert molecules. These molecules, as long as they are undissociated, behave very much like the atoms of the rare gases. The attractive forces of the atoms are so nearly satisfied by their combination with each other that the molecules do not condense to form liquids until low temperatures are reached.

Molecules of such chemical compounds as exist in the gaseous state must of course contain two or more atoms. As a rule the molecular formula is the simplest that can be written—that is, the molecule contains only one atom of that element which is present in the lowest atomic concentration. Molecular formulas of water vapor and hydrochloric acid, for example, are H_2O and HCl , instead of some multiple such as H_4O_2 or H_2Cl_2 . The attractive forces which make the atoms of these elements, hydrogen, oxygen and chlorine—unstable and disposed to double up in pairs—are satisfied by the chemical combination with each other.

In the accompanying Fig. 1 is shown schematically the arrangement of

the sodium and chlorine atoms in a crystal of sodium chloride, as determined by the X-ray spectrometer. Each sodium atom represented by a black circle is surrounded by six equidistant chlorine atoms represented by white circles. Similarly each chlorine atom is surrounded by six equidistant sodium atoms. If solid sodium chloride is heated sufficiently, evaporation takes place, the atoms leaving the surface in pairs in the form of sodium chloride molecules. It is evidently not possible to say which of six similarly related chlorine atoms will pair off with any particular sodium atom in the process of evaporation. The molecule of sodium chloride does not exist, as such, in the solid state.

In sulphur crystals the atoms are found to be arranged in a lattice structure in groups of eight. It is significant that these groups contain the same number of atoms as are found in the molecules of sulphur vapor. It seems certain that these groups of eight atoms must retain their identity throughout the changes of melting and boiling.

From the two examples just given it is apparent that the definition of a molecule in the solid state is difficult. In many substances like sodium chloride there is apparently no unit which can be called a molecule unless we call the whole crystal a molecule. Metallic elements all fall in this class. On the other hand, in sulphur and in a large number of chemical compounds, the solid crystal contains certain groups of atoms which may be regarded as molecules.

CHEMICAL FORCES

It has been customary to distinguish rather sharply between the chemical force called "affinity" and the physical forces of cohesion, adhesion, surface tension, etc. On considering the structure of the sodium chloride crystal, it is evident that the forces which are responsible for the cohesion of the crystal are the chemical forces, or the "affinity," between the sodium and the chlorine atoms. This is merely one example of a large mass of evidence which is forcing us to the conclusion that the physical and chemical forces between atoms are of the same nature and that there is no justification for a sharp distinction between them.⁴

The chemical forces which hold atoms together in the form of distinct molecules are very definite in respect to the number of atoms held in combination. An atom's combining capacity is expressed by the term valence; hydrogen possesses unit combining capacity, it is always held to have a valence of 1. Furthermore, the valence of hydrogen is considered to be positive, while that of the elements with which it combines is considered to be negative, at least in respect to hydrogen. Any element which can replace hydrogen in its compounds is also said to have a positive combining capacity. Oxygen is the standard for negative valence, having a combining capacity of 2, since one atom of oxygen combines with two atoms of hydrogen. These are simply the ordinary rules of valence, into which it is not necessary to go at further length here.

Simple molecules formed in accordance with these rules often combine with one another to form more complex compounds; typical examples are hydrated salts, and silicates. The numbers of molecules of each kind involved in these combinations are quite definite, but are not indicated by the ordinary rules of valence.

FIG. 1. SIMPLE CUBIC ARRANGEMENT STRUCTURE OF SODIUM CHLORIDE CRYSTAL

⁴"The Constitution and Fundamental Properties of Solids and Liquids," Irving Langmuir, *Journal, American Chemical Society*, 1916 and 1917.

There is nothing in the valence of the elements to account for the number of molecules of water in definite hydrates $\text{NaCl} \cdot 2\text{H}_2\text{O}$; $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$; $2\text{FeCl}_3 \cdot 12\text{H}_2\text{O}$; $2\text{FeCl}_3 \cdot 7\text{H}_2\text{O}$; $2\text{FeCl}_3 \cdot 5\text{H}_2\text{O}$ and $2\text{FeCl}_3 \cdot 4\text{H}_2\text{O}$. Ferric chloride forms a number of distinct hydrates, an illustration of a general tendency for molecules to combine with each other in several different ratios, each definite but apparently unrelated to the valences of the constituent elements or to each other.

Compounds of this type are usually limited to the solid state. Any attempt to volatilize a hydrated salt results in the decomposition of the compound, the water molecules and the salt molecules leaving the solid separately. There is no such thing as a distinct molecule of the hydrate itself, consisting of a definite number of atoms. The "molecule" in the solid state is the entire crystal, which is built up of its simple constituent molecules arranged in definite space lattices. The numbers of the different kinds of molecules which combine with each other in such arrangements depend upon geometrical considerations and not upon any definite combining capacity or valence characteristic of each molecule.

PRIMARY AND SECONDARY VALENCE

The forces which cause atoms to combine in definite proportions to form distinct molecules may for convenience be termed "primary valence" and the forces which unite these molecules into crystalline aggregates may be called "secondary valence" or "residual valence."

Secondary valence forces may serve to unite like molecules as well as unlike molecules. Thus, ice is built up of H_2O molecules. Two atoms of hydrogen are held to one oxygen atom in this group by primary valence. These molecules are then united by secondary valence in the crystal of ice. Ice is here not regarded as a distinct chemical compound, but merely as a different form of water; its formation from H_2O molecules is, however, a phenomenon of the same type as the formation of crystals of $\text{NaCl} \cdot 2\text{H}_2\text{O}$ from NaCl and H_2O molecules. The forces are equally chemical in nature.³

Molecules of the elements are primary valence compounds. The valence of an element toward other elements does not tell us how many atoms combine to form the molecule, but other considerations lead us to classify the forces involved as primary valence forces. The very existence of the molecule as a discrete particle passing probably unchanged through solid, liquid and gaseous states is typical of a primary valence compound. The heat of formation of molecules from like atoms is of the same order of magnitude as in the case of molecules formed from unlike atoms—that is, chemical compounds. The heat of formation of molecular hydrogen from atomic hydrogen, for example, is about 80,000 calories per gram-molecule. Heat evolved in reactions due to secondary valence is in general very much smaller and corresponds in magnitude with heats of fusion and evaporation.

Elements in the solid state are normally crystalline aggregates of the molecules of which they are constituted when in the gaseous state. Sulphur crystals are built up of molecules containing eight atoms each. Metallic elements are, as far as is known, monatomic in the gaseous state; accordingly the unit of which crystals of solid metals is constituted is an atom. The forces holding these atoms together are similar in kind to those uniting the molecules of sulphur in crystal-

line sulphur and the molecules of water in ice, the forces of secondary or residual valence.

COMPOUNDS BETWEEN METALS

Metals frequently form definite chemical compounds which are important structural constituents in alloys. It is a conspicuous characteristic of these compounds that their compositions are seldom indicated by the rules of primary valence. Probably the most important compounds of this class are Fe_3C and CuAl_2 . It is of course possible to write structural formulas after the manner of organic chemistry in which the ordinary rules of valence are satisfied. Thus the constitution

of CuAl_2 might be represented by the formula $\text{Al} = \text{Al}$. This would indicate that the crystals of this compound are built of molecules as units in the space lattice. It is probable that such is not the case, but that the units of the crystal lattice are the atoms of copper and aluminum arranged in definite and repeating patterns in which the atoms of copper and aluminum are not interchangeable. Since atoms of a pure metal do not combine with each other to form molecules, it seems quite likely that the atoms of two metals, which though different are nevertheless of generally similar chemical characteristics, likewise do not form primary valence molecules. Neither is the formation of intermetallic compounds accompanied by the large heat evolutions which so often accompany primary valence reactions. Furthermore, no intermetallic compounds are known to exist in the gaseous state, except for such feebly metallic compounds as the hydrides of antimony, arsenic and bismuth. These hydrides are composed of discrete molecules whose constitution is represented satisfactorily by the simplest possible formula based on the ordinary rules of valence. Therefore, the majority of intermetallic compounds seem to be secondary valence compounds whose compositions are determined by geometrical considerations such as the sizes of the atoms and the directional properties of their force fields, just as in the case of the hydrates discussed above.

MECHANISM OF SOLIDIFICATION

Liquids as well as solids must be held together by secondary valence forces. Gases consist of molecules in such a violent state of thermal agitation that the attractive forces between them are not strong enough to cause even temporary combinations. In the liquid state the energy of thermal agitation has decreased to such an extent that the collisions between molecules result in the formation of groups held together by secondary valence. Further collisions break up these groups so that their existence is only temporary and in actual time extremely brief. Liquids owe their fluidity to this constant shifting in the bonds between molecules. As the temperature is further lowered, the life of these molecular groups and the average number of molecules in them increase. Finally a point is reached at which the thermal energy of the individual molecules is not great enough to free them from the attraction of other molecules, and solidification takes place. The expansion of water which takes place on cooling from 4 to 0 deg. C. suggests the formation in the liquid of considerable molecular groups having the increased volume characteristic of crystalline ice. The metal bismuth also expands on solidification and we should therefore expect a slight expansion of the liquid immediately before solidification,

as in the case of water, or at least a decrease in the rate of fluid contraction.

The constriction of thermal motion can be accomplished by an increase in external pressure as well as by a decrease in temperature. If solidification takes place with a decrease in volume, as is the case with all the common metals except bismuth, the application of external pressure hastens solidification—that is, causes it to take place at a higher temperature. When solidification is accompanied by expansion, increase in pressure lowers the freezing point, but the actual changes in freezing point caused by changes in pressure are very slight.

We may review this discussion by the consideration of an example. Let us suppose some metallic tin is heated to a temperature of 2,500 deg. C. Under normal atmospheric pressure the tin will be in the gaseous state, since it boils at about 2,270 deg. C. To the best of our knowledge the gas is monatomic—that is, the molecules consist of single atoms. These atoms are in constant motion in straight lines, interrupted only by collisions. Each atom is surrounded by a field of force which attracts it to the other atoms with the same intensity as in the solid state. The kinetic energy, both of translation and rotation, overcomes the attractive forces, and no combination of atoms takes place. On cooling, this kinetic energy decreases until the attractive forces sufficiently overbalance it to cause the condensation of the gas to a liquid. Since the volume change is very much greater on passing from the gaseous to the liquid state than on passing from the liquid to the solid state, the effect of pressure on the boiling point is very much more marked than on the melting point. In liquid tin the atoms are held together by cohesion bonds of the secondary valence type, constantly breaking and re-forming, so that the positions of the atoms with reference to one another are not fixed. The liquid is therefore mobile, and can change its shape indefinitely without losing its continuity.

The atoms of tin are constantly tending to orient themselves into a regular pattern, a tendency which is

opposed by the energy of thermal motion. When this energy is sufficiently reduced, by cooling to 232 deg. C. the orienting or crystallizing tendency gains the ascendancy and solidification takes place. Solidification is identical with crystallization, or the arrangement of atoms into positions fixed with relation to each other. The atoms remain in a state of vibration about their equilibrium positions, but have probably lost their energy of rotation. On further cooling the amplitude of vibration decreases, causing a contraction of the metal. As the kinetic energy of the atoms decreases and they become closer together, it requires a greater external force to separate them—that is, the cohesion increases.

Crystals which form on solidification grow outward from nuclei until they meet each other along surfaces which are necessarily irregular. Some of the molten tin remains between the crystals in an unoriented or amorphous condition. On cooling to room temperature the motion of the atoms of the amorphous metal decreases to such an extent that the material, although possessing many of the structural features of a liquid, becomes rigid and is in effect a solid. However, the atoms retain their ability to change their position with relation to one another, and the substance is therefore capable of flow. Transition from a liquid to an amorphous solid is gradual and there is no sharp freezing point and no heat of solidification; an amorphous solid is doubtless an undercooled liquid.

COMPRESSION

T. W. Richards⁵ has pointed out that the attractive forces between atoms act in many ways like the application of external pressure. "There is strong evidence that where affinities are great the atomic centers come closer together, and that where the affinities are slight they are further apart." Richards considers the atom as including the entire "sphere of influence," or space

⁵"The Present Aspect of the Hypothesis of Compressible Atoms," Theodore W. Richards, *Journal of the American Chemical Society*, December, 1914.

FIG. 2. RELATION BETWEEN MELTING POINTS, THERMAL EXPANSIONS, ATOMIC VOLUMES AND COMPRESSIBILITIES OF THE ELEMENTS (ACCORDING TO T. W. RICHARDS)

dominated by the atom. On this basis atoms must necessarily be regarded as compressible in order to account for the compressibility, expansibility, etc., of solids. The volume of an atom is then a definite quantity, depending on the pressure to which it is subjected.

This pressure may arise from external forces or from interatomic attraction. In the latter case it is spoken of as an internal pressure, and substances held together by strong affinities are said to be under high internal pressure. A striking example of compression by chemical affinity is found in the case of potassium chloride. The atomic volume of potassium is 45 (c.c. per gram-atom) and the molecular volume of KCl is 37 (c.c. per gram-molecule). In the compound the potassium atom and the chlorine atom together occupy less space than does the potassium atom alone in solid metallic potassium. This contraction is held to be due to a high internal pressure caused by the strong affinity of potassium for chlorine.

Small atomic volume is thus evidence of high internal pressure, which should be accompanied by great cohesion. The same forces that resist the separation of atoms by mechanical tension also resist their separation by thermal agitation, therefore small atomic volume should in general indicate low coefficient of thermal expansion, high boiling point and high heat of vaporization; such assumptions are verified in a most remarkable way in the diagram,⁶ Fig. 2, collecting the experimental evidence now available.

The volume of any substance is diminished by the application of hydrostatic pressure. If we suppose all solids to be inherently under internal pressure, then the actual effect of a given absolute increment of external pressure, such as 1,000 lb. per sq.in., must be greater the less the initial internal pressure. The fixed increment of pressure will be effective in proportion to its ratio to the total internal plus external pressure on the substance, and those elements whose internal pressures are low, as shown by high atomic volumes, should have high compressibilities.

INFLUENCE OF ATOMIC VOLUME ON THE CONSTANCY IN COMPRESSIBILITY

"In a system already under great pressure each small successive addition of pressure will be nearly the same percentage of the whole, and therefore each like addition would be expected to have very nearly the same effect upon the volume. On the other hand, if the substance is under small pressure, each successive equal addition of pressure will be a much smaller percentage than the preceding and would, therefore, have a greatly diminished effect upon the volume. Thus, if the compressibility decreases greatly with increasing pressure, one may infer that but little pressure was present in the first case, but if a body possesses a small compressibility which is nearly constant over a wide range of pressure, we should feel obliged to believe that a great internal pressure was already present in some form within the substance." Accordingly, substances which, like carbon, silicon, iron, etc., possess low atomic volume and low compressibility, should also show considerable constancy in compressibility with varying pressure.

These relations are actually found to hold with considerable regularity in the case of elementary sub-

stances, and, "Consistently, elements with great atomic volumes also show, in general, great volatility, great compressibility, great coefficient of expansion, and great change of compressibility with increasing pressure."

Cleveland, Ohio.

Chemical Warfare Exhibit in Washington

THE importance of chemistry in national defense and industrial independence is strikingly shown in an exhibit in the offices of the National Research Council in Washington, D. C. The exhibit was arranged by the Chemical Warfare Service and will be open to the public for a month or six weeks. After that time it is proposed to take it to Philadelphia and New York.

While most chemists and some of the United States Army officials realize that chemistry as applied to warfare is the most powerful of all modern weapons for national defense, the country at large—the average citizen—is apparently ignorant of this fact. To the average layman chemistry is a jumble of incomprehensible names and symbols, and chemical warfare is associated in his mind with hideous atrocities. Up to this time scarcely any effort has been made to educate the public not only as to the value of chemistry in national defense but also as to its importance in peace time. It is the purpose of this exhibit to assist in eliminating the false impressions that prevail and to show by novel graphic representations how national prosperity is dependent on the proper development of the chemical industries and how these industries in time of war provide the only adequate means of national defense.

The main feature of the exhibit is a topographic model (Fig. 1), 7 x 12 ft., of an idealized group of chemical industries whose development and maintenance are essential for adequate national defense. The outer portion of the model shows the plants and equipment required for the production of some of the more important crude materials which are required by the chemical industries. This includes models of sulphur wells; a sulphuric acid plant; a coal mine with the usual equipment for sorting and handling coal; a byproduct coke oven with stills and storage tanks for the various crude products obtained from coal tar; a hydro-electric power plant which supplies electric power to a plant for the production of nitric acid from atmospheric nitrogen and also to an electrolytic chlorine plant from which caustic soda and chlorine are produced by the electrolytic decomposition of salt; and salt wells which provide the salt for the chlorine plant.

This group of plants surrounds what may be called the heart of the chemical industry—that is, the plants which produce the intermediate and finished chemical products. The group of buildings representing the production of the intermediate chemicals is situated near the center of the model. Radiating from the intermediate chemical plant are four separate groups of factory buildings. One group represents an industry for the manufacture of dyes; another for explosives; another for pharmaceuticals and medicinals, and another for war gases. All of these four industries use the same chemical intermediates for the production of their finished products.

Back of this model are four charts (Figs. 2 to 5) showing some of the intermediates and finished products obtained from each of the four crude chemical materials—sulphur, salt, coal, and atmospheric air. On

⁶From an article by T. W. Richards on "The Compressibilities of the Elements and Their Relations to Other Properties," *Proc. National Acad. Sciences*, vol. 1, p. 411, July, 1915.

these charts actual samples of the chemical substances are attached.

Other features of the exhibit are samples of the material used in chemical warfare, such as gas shells, gas masks, Stokes mortars, Livens projectors, complete collections of all the war gases used in the late war, samples of pharmaceuticals, medicinals, perfumes and dyes, with various dyed materials. All the products exhibited were made in the United States.

Another feature is a collection of models illustrating the arrangement of atoms in the molecules in various coal-tar products, thus showing the chemical similarity of dyes, war gases, explosives and pharmaceuticals. Examples of these models are given in Fig. 6, which illustrate the chemical structures of carbolic acid and picric acid respectively. This shows the similarity in the structures of these two chemicals and simplifies the explanation necessary to show the non-chemist how picric acid is produced from carbolic acid.

All these features are explained in detail in a booklet which is given to each visitor. The booklet also contains an article by Edwin E. Slosson on "What the Chemist Has Done and May Do in War and Peace." In it he says:

"The Great War forced America into a new industrial field, the manufacture of organic chemicals. When our soldiers met the enemy on the battlefields of France they had to fight fire with fire and poison gas with poison gas. At the same time the home folks found themselves without the dyes and drugs that they had hitherto obtained from Germany. It became necessary then to create

chemical industries of all sorts from optical glass to nitrates and this was done, but with haste and waste, for enterprises which should have been a gradual growth had to be extemporized in a year. But by the time the fighting was over the gigantic task was accomplished and the United States was for the first time 'free and independent' so far as most of the essential chemical products are concerned.

"Now that we have got this chemical industry the question is, What shall we do with it? Shall we again place the weapons needed for self-defense in the hands of possible enemies and shall we once more turn over to our commercial rivals the keys to our most important manufactures?

"The answer to this vital question can only be given by the American people and they will only be qualified to decide when they know the extent and importance of the chemical industry and how it may be kept at home. If now it had been a piece of land that we had acquired through the war, say the little island of Yap, we could have kept it by a few forts and ships. But science is more slippery. It does not stand still but keeps moving—and in the case of chemistry moving very rapidly. The only way to keep it is to keep ahead in it. The American dye maker now has at his disposal all the German patents, but the German chemists have not stopped using their brains and unless we use ours we shall soon be left behind. Of what value was the best patent on a flint-lock the day after the percussion cap was invented? As soon as the Germans found out how to make artificial indigo, the indigo crop of India

From salt

lost its value. The chemical industry is the offspring of science and dies if weaned from its mother.

"In the model are four groups of buildings looking very much alike because they are much alike, yet, as the labels state, the first may be turning out explosives, the second pharmaceuticals, the third war gases and the fourth dyes. This correlation of the chemical manufactures is a fortunate thing, for it means that while we are developing one of our essential home industries we are at the same time making the most effective provision for national defense. A warship is of no use except for war. But a chemical plant producing dyes may readily turn out explosives in an emergency and the making of medicines must go on in peace time and war time. Young men drilled in the art of presenting arms and forming fours may never have occasion to use this knowledge, but young men trained as chemists may make the most effective combatants as well as the most useful of citizens. The development of American chemical industry is a policy that commands the support of pacifist and militarist as well as of all the rest of us who come somewhere in between.

"The cost of a single battleship, about \$30,000,000, would endow an establishment for chemical research such as the world has never yet seen, and the expense of keeping the battleship in commission, about \$3,000,000 a year, allowing for depreciation, would pay for the education of all the chemists the country could need.

FIG. 6.

Models showing the arrangement of the atoms in the molecules of carbolic acid (right) and picric acid (left). The different atoms in the molecules are represented by different colored balls.

The modern battleship is made as invulnerable as possible but the men on it are not invulnerable. No armor can keep out air and a ship does not have to be sunk if the crew is suffocated. A sharpshooter wastes no more ammunition on a riderless horse. A single airplane with a couple of men may sail over a warship at an unassailable height and besprinkle its decks with a liquid so corrosive that three drops of it touching a man's skin at any part will kill him and so persistent that such little of it as may be caught in crevices will render the ship uninhabitable for days. A 14-in. shell pursues a single course and when it explodes that is the end of it. An ounce of diphenyl-chlor-arsine, an innocent looking white powder, will keep up its bombardment for weeks and its molecular projectiles will fly around corners and into the smallest cracks.

"Armed with such liquids and solids the airman of the next war will not need a machine gun or even bombs to attack the enemy underneath. He does not have to take accurate aim and calculate the allowance for wind,

height and velocity. All he need do is to attach a sprayer to the tail of his machine and rain down poison on the earth beneath as the farmer kills the bugs on his potato field."

It is hoped that this exhibit will enable the public to visualize the importance of chemistry to the nation, that it will show the necessity of building up an adequate Chemical Warfare Service, of developing chemical industries which will make the United States independent of foreign countries, of encouraging basic industrial chemical research and the training of a personnel capable of making this country the most powerful chemically both in war and in peace-time pursuits. The lesson sought to be taught is that any country that hopes to hold its own in peace or war must have an adequate chemical industry guided by scientific research and backed by patriotic public opinion.

United States Crude Oil Production in 1920

The following tables give a brief résumé of the crude oil situation in the United States for the past year:

INCOME AND OUTGO (Stated in Barrels)

	Domestic Production	Domestic Consumption	U. S. Imports	U. S. Exports
1920*	443,402,000	437,579,000	106,175,000	8,045,000
1919*	377,719,000	375,559,000	52,822,000	5,924,000
1918	355,927,716	380,242,153	37,735,641	4,900,691

Sugar Imports in 1920

From the reports of the Department of Commerce Lamborn & Co. has compiled a tabular study of the sugar supply during 1919 and 1920. The following summary of the report as published recently in the *Journal of Commerce* shows how the high prices prevailing during 1920 increased the amount of sugar imported from unusual sources.

	Sugar Imports, Tons	
	1920	1919
Normal sources:		
Cuba	2,572,389	2,984,885
Porto Rico.....	368,798	325,175
Hawaii	490,906	506,692
Philippines	134,721	78,514
Total from normal sources.....	3,566,814	3,895,266
Other sources:		
Far East and Africa.....	380,512	0
South America.....	233,480	15,643
West Indies, exclusive of Cuba and Porto Rico.....	107,993	3,567
Europe	53,706	0
Central America.....	43,412	7,633
Canada	29,738	0
Mexico	27,759	0
Egypt	7,438	0
Newfoundland and Labrador.....	54	0
Total from unusual sources	884,092	*70,391

*Includes imports from countries which did not send any sugar to the United States during 1920.

Gas Furnaces for Melting Non-Ferrous Metals

BY M. A. COMBS

FOUNDERS, smelters and refiners realize the prime importance of the melting department. The character of the product, casting or ingot, and its cost are directly dependent on the fuel and furnace used. While this realization is general, it is also frequent that a thorough investigation into the various fuels and furnaces to meet the particular requirement has not been made. The great adaptability of gas in the particular furnaces to be used for the various classes of melting is so striking that an exposition will show this fuel to meet every demand most satisfactorily. Gas is often used as the fuel for pit furnaces formerly fired with solid fuel and for all types of open-flame or non-crucible furnaces. Particular advances have recently been made in melting brass aluminum and other alloys in a crucible furnace specially designed for gas fuel and in the gas-fired spherical type of non-crucible furnace. These two furnaces provide a medium for melting all kinds of non-ferrous metals, the choice depending on the scale of the work and character of the metals melted.

NON-CRUCIBLE FURNACE

Oil burning in an open-flame or non-crucible furnace where the flame comes in direct contact with the metal is attendant with excess air and an oxidizing atmosphere. Even with a frequently tilted furnace it does not take much of a metallurgist to know that an oxidizing atmosphere within such a furnace will not produce the best metal. A spherical furnace of this type is ideal, too, for smelters and large foundries. It is a sole question of burning enough fuel in this furnace with a non-oxidizing atmosphere to get the best product. Gas answers this purpose. Its freedom from sulphur is also an advantage over much of the fuel oil now used.

APPLICATION OF THE FUEL

The gas is fed to the furnace at low pressure mixed with just the right amount of air to burn it and no more. After determining the character of the flame and setting the adjustment at the proper relation of gas to air to give a neutral atmosphere within the furnace, the mixture may be controlled by one valve, proportioning the air as the gas is turned up or down. For best practice the burner nozzle is fired on a tangent to the lining of the furnace, well cemented into the furnace or fired to a hole. The pipe containing the mixture of gas and air should be run without reduction up to the nozzle with a minimum bend and rigidly fastened to the tilting furnace from a swing joint on the trunnion of the furnace.

Spherical type of gas-fired tilting furnace is made in various capacities from 500 to 8,000 lb. It is mounted on trunnions at such a height as to give plenty of room for pouring. It is tilted not only for charging and pouring but also during the heat at frequent intervals. The charging door is closed during the heating, the vent being through the pouring hole. The furnace of 1,000-lb. capacity is used with gas as a fuel in foundries for red brass and yellow brass and in smelting with wonderful results.

In making "G" metal a foundry in one of the large

New England shipyards required forty-two minutes per melt of 1,100 lb. of metal, and burned 310 cu.ft. of 600 B.t.u. gas per 100 lb. of metal.

A well-known die-casting company making yellow brass in a spherical furnace makes seven heats in six hours, melting 5,800 lb. with a gas consumption of 269 cu.ft. per 100 lb. Dross amounted to 3.74 per cent.

These figures show for the average of "G" metal and yellow brass a fuel cost of 35c. per 100 lb. of metal melted with gas at \$1.20 per 1,000 cu.ft.

The character of the metal is such as to meet the highest specifications, it is melted economically and with the best of operating conditions as to speed, cleanliness and comfort to the melters. The simplicity is extreme, and the possibilities of this furnace are wide indeed. Its use will decrease lost motion in foundry practice. It simplifies the production problem at the start and from the melting on speeds up and simplifies casting and ingoting.

Discussion of general foundry practice may not belong to the consideration of gas as the fuel; however, the fuel is the controlling element in the furnace and the melting unit profoundly affects the subsequent foundry operations. The potentialities of the large gas furnace to improve foundry practice, from the melting unit on, are evidently worth thinking about.

GAS VERSUS ELECTRICITY OR OIL

In comparing gas against electricity for melting furnaces the most striking advantage of gas after its economy is the flexibility of the furnace. Any alloy may be melted in a gas furnace without changes, excepting rarely a relining in the non-crucible type—no changes at all are necessary in the crucible type. This is true no matter whether a high lead, high zinc or any other difficult composition of copper or aluminum alloy is melted. There are some alloys which it is no easy matter to charge into an electric furnace, and some copper alloys which probably cannot be so melted.

Oil at present is equal to if not more expensive than gas in fuel cost alone. When the cost of oil was more favorable, the factors which even then gave gas an advantage were cost of storage, cost of preparation, crucible or lining life and metal shrinkage. These facts will be further brought out in comparative figures. However, there are certain advantages of the use of gas that do not appear in using any other fuel. Gas does not need to be stored, an economy of space and overhead, and it is not paid for until used, a further saving on investment. Due allowance should be given for these facts when considering the fuel question.

GAS CRUCIBLE FURNACE

The crucible pit furnace fired with coal or coke has long been the melting unit in non-ferrous foundries large and small. In many cases, particularly in the small foundry, it is still desirable to use a crucible furnace. However, pit furnaces with solid fuels are certainly not the speediest method of melting metal, even if they have done much good work in the past. Their continued existence is not justified merely as survivors of the days when metal founding was a black art. In economy of space alone a battery of gas-fired crucible furnaces takes only one-third the room needed for the solid-fuel furnace, a figure that does not include saving of space needed to store fuel. Two to three heats per furnace is the average of the pit fire as against eight heats per day with gas. For this class of melt-

FIG. 1. A BATTERY OF GAS CRUCIBLE FURNACES
FLUE-CONNECTED

ing one of the most important advantages to credit to gas is that it is not necessary to have the furnace started in the early morning hours in order to pour the first heat when the molders are ready for the metal. The first heat can be taken out of the gas furnace in about an hour, which means that the melters do not have to start work any earlier than the molders. When figuring in the attendant costs of other fuels, such as labor, time and shrinkage, and allowing for storage and preparation, the result shows that while the cost per B.t.u. in the case of gas is naturally higher, the cost per pound of metal melted, or the unit production cost, is lower.

DESIGN OF FURNACE AND APPLICATION OF FUEL

The properly designed crucible furnace for gas fuel is a cylindrical furnace with an interior diameter just large enough to admit the tongs, when removing the crucible. The crucible is set on a block at such height that the top of the crucible is not more than 2 in. below the furnace cover. The crucible block is graded toward a slag hole so that splash metal will not collect in bottom of furnace.

In firing a crucible furnace with gas, the fuel should be fed to the furnace mixed with the proper amount of air for perfect combustion, this mixture being controlled by one valve. A burner nozzle directing a fire tangent to the lining of the furnace at the bottom of the crucible gives the best distribution of heat and prevents localized heating of the pot. This method of firing is most effectually done by firing to a hole, the furnace being so designed that the amount of back pressure prevents sucking in secondary air around the nozzle. The advantage of firing to a hole against imbedding the nozzle in the refractory wall is that it prevents burned nozzles and the necessary care in cementing them in.

The ordinary type of furnace has a flat refractory cover with a central hole for charging metal into the pot and as a vent for the products of combustion. The fumes from the metal escape through this hole and it is necessary to have a hood to take the fumes out of the room. In melting red brass this is not so necessary, as the fumes are not as objectionable and harmful as those of yellow brass, or a copper:lead alloy.

From the last two alloys a gas furnace may be

COMPARATIVE FIGURES FOR CRUCIBLE MELTING

Fuel cost:		
75 lb. of coal per 100 lb. of metal at \$16 per ton.....		\$0.60

Oil, 1 hour at 70c. per hour.....		.70
Gas, 1 hour at 70c. per hour.....		.70

Summary of total costs per 100 lbs. of metal melted:

	Coal	Oil	Gas
Fuel.....	\$0.60	\$0.40	\$0.60
Crucible.....	.266	.21	.16
Shrink.....	1.05	.90	.75
Labor.....	1.40	.70	.70
	\$3.316	\$2.21	\$2.21

specially designed with a hood incorporated in the cover. This furnace cover is flue-connected, the fumes passing directly into the pit flue and out by an overhead flue. This type of cover also acts as a preheater in that the charge for the crucible may be placed in it and the products of combustion passing through it to the flue preheat the charge, effecting greater economy in fuel. A battery of six of these furnaces is shown in Fig. 1. They each hold a No. 80 crucible which has a capacity of 300 lb. of 50 per cent copper and 50 per cent lead.

OPERATING FIGURES—GAS CRUCIBLE FURNACE

Two furnaces, similar to the ones shown in the illustration, melting 50-50 copper and lead alloy in a foundry in the metropolitan district, show a fuel consumption of 400 cu.ft. of gas per 100 lb. of metal. This foundry also melts aluminum in the same furnaces.

A foundry in New England using four of these furnaces with No. 80 crucibles runs five heats of brass and eight heats of aluminum per furnace per day with a gas consumption of 6,700 cu.ft. per furnace per day. Thus 1,000 lb. of brass, or 1,000 lb. of aluminum, may be melted at a fuel cost of \$8.71 with gas at \$1.30 per 1,000 cu.ft. In this foundry one crucible has been used over fifty heats, a particularly long life for a crucible, even in a gas furnace. The shrinkage on the brass is only 2 per cent, a figure which is, however, not exceptional in gas crucible furnaces.

The accompanying table shows a day's run in a foundry in New York City melting 85-5-5 brass.

DAY'S RUN, NO. 40 CRUCIBLE FURNACE

No. Heat	Time Started	Time Finished	Time per Heat, Minutes	Lb. Metal Melted	Cu.Ft. Gas per Heat
1	8:40	9:30	50	105	500
2	9:40	10:21	41	105	375
3	10:30	11:10	40	105	320
4	11:19	11:49	40	105	280
5	12:00	12:30	30	105	300
6	12:40	1:12	32	105	280
7	1:24	1:56	32	105	250
8	2:05	2:33	28	105	300
Totals			293	840	2,605

Average time per melt $293 \div 8 = 35$ minutes.

Gas consumption, 310 cu.ft. per 100 lb. of metal melted.

Another foundry reports the following figures in brass melting: Metal melted, 848 lb.; gas consumption, 3,026 cu.ft.; metal loss (shrinkage), 2.25 per cent; fuel cost, 350 cu.ft. per 100 lb. gas at \$1 per 1,000 cu.ft., or 35c. per 100 lb.

Since the final cost per unit of production is less with gas than any other fuel, it is the most economical fuel.

Investigations of the Chemical Literature—III

Patent Searches—Facilities for Investigation Offered by the Patent Office—Official Publications Relating to Patents—Obtaining Copies of United States and Foreign Patents—Importance of Providing Better Facilities for Training in the Use of Chemical Literature*

BY FRANK E. BARROWS

Patents

PATENTS, from their very nature, require consideration from various aspects other than as a part of the chemical literature. Thus the patentability of inventions, the filing and prosecution of applications for patents, the construction, validity and scope of issued patents, questions of infringement of unexpired patents, patent litigation, property rights in patents, the rights and obligations of patentees, etc., are matters primarily involving patents as patents rather than as publications, and are matters requiring consideration from the standpoint of the relevant principles of the patent law applicable thereto, as well as from the standpoint of the chemical principles that are involved.

Patent searches or investigations may thus be of a special character. In considering questions of infringement, for example, the primary search extends only through the United States patents granted during the last seventeen years (the term of a United States patent), and requires consideration of the invention claimed rather than, or in addition to, the invention described, but inasmuch as the claims of a patent may require to be construed by the accompanying description and in the light of the Patent Office proceedings leading up to the grant of the patent, as well as in view of the prior state of the art disclosed by prior patents and publications, and in accordance with relevant principles of the patent law, a more extended search to include expired United States patents and other patents and publications may be important or even essential.

Investigations of the patentability of inventions, such as are made to determine the advisability of making application for patent, or by the Patent Office examiners in determining the patentability of inventions set forth in patent applications, as well as investigations of the scope and validity of issued patents, may likewise require an extended search of the prior patents and publications, to determine whether the invention is new and whether it is a patentable invention or discovery, within the meaning of the patent law.

Patent investigations thus include both investigations of patents as patents, and investigations or searches of patents as publications and as a part of the chemical literature.

THE PATENT LITERATURE

Considered as a part of the chemical literature, the patent literature furnishes one of the most important fields of search, inasmuch as it records the inventions and improvements, and hence the progress, made in almost all fields of chemical industry. Not infrequently inventors have patented their inventions without having published any descriptions of them elsewhere and with-

out any abstracts or digests of their inventions appearing in the periodical literature. The patent literature therefore contains much that is not available elsewhere.

UNITED STATES PATENTS

More than 1,300,000 United States patents have been granted, of which a very considerable number relate to chemistry and allied subjects. A proper classification of these patents is therefore indispensable for search purposes. The classified patents, however, are available only at the Patent Office at Washington, and for this reason comprehensive searches through the various classes of United States patents can be satisfactorily made only in Washington.

The classification of United States patents, so far as it is official, is set forth in the "Manual of Classification"; in the "Definitions of Revised Classes and Subclasses," and in the "Classification Bulletins" which are issued semi-annually by the Patent Office.

The "Manual of Classification" gives instructions for searching the classified United States patents, together with a list of classes and subclasses and an index of class and subclass titles. It is in constant use by those making searches at the Patent Office. Copies of this manual may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C. The price is 50c.

The work of classifying U. S. patents, of which there are about three hundred separate classes and thousands of subclasses, has been largely conducted by the classification division of the Patent Office. A history of this division and of its work and methods of classification is given in the "Report of the Investigation of the United States Patent Office," made by the President's Commission on Economy and Efficiency (published in 1912 as H.R. Document 1110, Sixty-third Congress, Third Session). A short description of the Scientific Library of the Patent Office and of the search room, as well as of the card index of Chemical Literature, is also given in this report (Appendix K).

The difficulties in making a satisfactory classification of patents for search purposes is complicated by the different kinds of patent searches required—whether novelty, validity or infringement—and this difficulty is well recognized by the Patent Office. There has been at times an unfortunate tendency in the classification of chemical and related patents to disregard the prevailing classification of the other chemical literature, and to use unusual terms and make unusual lines of distinction, which the average chemist does not readily recognize and which may even give trouble to the experienced patent searcher.

OFFICIAL CLASSES AVAILABLE AT PATENT OFFICE

As is to be expected, the chemical patents are classified in more or less definite and distinct classes, and

*For Parts I and II see CHEM & MET, ENG., vol. 24, Nos. 10 and 11, pp. 423 and 477, March 9 and 16, 1921.

are segregated, for purposes of examination, in a few examining divisions. The official classes of patents are accessible in the public search room of the Patent Office. Duplicate sets of classified patents are provided in the examining divisions. Many of the chemical classes of patents have never been officially reclassified, and the present official classification is often unsatisfactory for search purposes. Some of these classes have, however, been in part unofficially reclassified by the examiners who have examined them, so that a more satisfactory classification will be found in the examining divisions. It is thus quite common for different examiners to have special subclasses or digests of patents, both United States and foreign, as well as of other publications, along the lines which they have occasion to search. Some of these unofficial classes and digests are of very great value, but unfortunately they are not accessible except in the examining divisions, and with the permission of the examiners.

OTHER FACILITIES OFFERED BY PATENT OFFICE

In making searches at the Patent Office at Washington, not only does the searcher have available the classified United States patents, but he has access to the files of such patents containing the various Patent Office proceedings leading up to their grant, including the original application papers and amendments thereto, and the official communications of the examiners who examined the application, in which are referred to the prior patents and publications which the examiners found upon their search and considered relevant to the invention sought to be patented. By examining the files of United States patents which are of nearest subject matter to the investigation in question, it may be possible to obtain reference to prior patents or publications which are of particular interest and which would not be readily available otherwise.

A further value of the patented files is the indication therein of the classification of the respective patents and the indication in the various official actions of the classification of the prior patents which are referred to therein. Attention may thus be directed not only to prior patents of relevant subject matter, but even to other classes of the Patent Office which might otherwise have been overlooked but which may contain patents of interest. The number of classes and subclasses of patents is so great and the classification of patents is in many instances so complex that relevant classes or subclasses may well be overlooked unless special precautions are taken to insure their proper consideration.

Likewise available at the Patent Office are the records of interference proceedings in which issued patents have been involved—records which in some cases contain lists of prior patents and publications relating to the same subject matter as the patent, in others testimony of interest in connection with the patented invention.

COURT RECORDS OF PATENT CASES

Valuable information may likewise be obtained from many of the court records of patent cases and even from the court decisions in such cases, inasmuch as a consideration of the question of patentability, in view of prior patents and publications, is almost always raised in such cases. Extended searches are usually made in connection with such litigation and the pertinent results thereof made a part of the record of the case. The testimony forming a part of court records may likewise contain valuable information.

Attempts to make comprehensive investigations of United States patents elsewhere than at the Patent Office are generally unsatisfactory. However, abstracts of United States patents, as well as foreign patents, are published in *Chemical Abstracts*, classified in the same way as the other literature and similarly indexed, and a search through this field is a useful check upon any search made at the Patent Office itself. Nevertheless, experience has shown that a search through *Chemical Abstracts*, even during recent years, cannot be relied upon to disclose all patents of interest along any particular line, and, of course, the *Abstracts* go back only to 1907.

PARTIAL LISTS OF CHEMICAL PATENTS

There has been no comprehensive list published of United States patents relating to chemistry.

A valuable digest of the older United States patents relating to chemical industry has been published in Census Bulletin 210 (pub. 1902), but this list includes only patents granted prior to 1902, and hence only expired patents. Although the bulletin is now out of print, this list was also published as an appendix to Census Reports, Vol. X, Twelfth Census of the United States, Manufactures, Part IV, Special Reports on Selected Industries.

One of the few partial lists of United States patents that have been published appears in a German publication—viz., in vol. 3 of Winther's "Patente der organischen Chemie" (pub. 1910). This list includes patents relating to organic chemistry granted between 1895 and 1908, with the number, date, patentee and title of the patent, and the number of the corresponding German patent, if any.

Another of the partial lists of United States patents published is that of patents granted to Germans and Austrians, compiled by the Federal Trade Commission as *prima facie* enemy-owned patents. This list, or the part of it of more particular relation to chemistry, has been published by the *Oil, Paint and Drug Reporter* during the past year, and also appears in the "1918 Year Book" of that periodical.

A similar list of formerly enemy-owned patents, which have been taken over by the Alien Property Custodian and transferred to the Chemical Foundation, is contained in a "Temporary List" issued by the Chemical Foundation. This list includes about four thousand patents now in force, that is, granted during the past seventeen years.

All of these lists are at best but partial and incomplete, and unsatisfactory from the standpoint of making any comprehensive search.

BRITISH PATENTS

British patents have been granted since 1617, and as early as 1622 we find patents relating to chemical subjects—viz., the manufacture of soap and of white and red lead pigments. Prior to the year 1700, patents were also granted relating to various other chemical subjects, including alum, salt, pottery, the parting of silver from lead, saltpeter and various metallurgical processes.

The British patents are more generally accessible for purposes of search than the patents of any other country, for the reason that the British Patent Office has published classified abstracts or abridgments of all the patents which have been granted since the earliest days of the British patent system and up to within the last

digests or abridgments of British patents granted between 1622 and 1866 relating to "acids, alkalis, oxides and salts"; another volume containing digests or abridgments of British patents granted between 1617 and 1866 relating to "oils, fats, lubricants, candles and soaps," and so on.

Between the years 1855 and 1908 the classified British patents of each class have been published in nine successive volumes, each covering a period of a few years, so that, for example, the nine volumes of the class relating to "acids, alkalis, oxides and salts, inorganic," will contain abstracts or abridgments of the British patents of this class granted during this period. A similar series of nine volumes contains abstracts or abridgments relating to organic chemistry, and the same is true of metallurgy and other various classes into which the British patents are officially classified. The classified abridgments since 1908 are being published a few pages at a time.

In addition, fifty-year subject-matter indexes of the classified British patents have been published for each class, covering the period from 1861 to 1910.

GERMAN PATENTS

A complete set of German patents is available at the Patent Office in Washington, and in addition, a classified set of German patents for recent years, classified according to the German classification. A search of German patents can accordingly be much more readily conducted at Washington than elsewhere.

However, many of the German patents are abstracted in the German abstract and review periodicals, and in addition many compilations of German patents, relating to different subjects, have been published. Notable among these is the work by Friedlaender, relating to dyestuffs. This work, which has been issued in twelve parts and which covers the period from 1877 to 1916, gives a very complete and classified review of the German patent literature relating to organic dyestuffs.

A similar work is the three-volume compilation by Winther, "Patente der Organischen Chemie." This work is not so well known as Friedlaender's, but it is in some respects more accessible for search purposes. The first volume contains abstracts or digests of the German patents and applications between 1877 and 1905, relating to organic compounds other than dyestuffs. These are classified according to subject matter—for example, hydrocarbons, alcohols, ketones, alkaloids, photographic developers, etc.

Vol. 2 contains abstracts or digests of German patents relating to organic dyestuffs within the same period, 1877 to 1905, and these patents are classified according to classes—for example, sulphur dyes, indigo dyes, azo dyes, etc.

The third volume, published in 1910, is the index volume, and contains several different indexes, including a numerical list of German patents relating to organic chemistry, with the corresponding United States, English, French, Austrian and Russian patents, if any; also a list of United States patents (organic chemistry) between 1895 and 1908 with the number, date, patentee and title of the invention and the corresponding German patents, if any. Similar lists are given of the British, French, Austrian and Russian patents, with the corresponding German patents, if any. The volume also contains a list of patentees, with the patents of each patentee and of each company classified by subjects. The volume includes finally a subject-matter

index of the various organic compounds, intermediates, etc., with reference to the volume and page of the first two volumes of the work where they will be described.

A useful list of trade names of chemical compositions and products of various kinds is also included in this same volume (Winther, vol. 3), with indication of the chemical composition, manufacturer, and the patent or literature citation where a description of the substance will be found.

OTHER FOREIGN PATENTS

The patents of some of the other foreign countries, including France, Austria, Switzerland, Denmark, Norway and Sweden, are likewise available, in classified and bound form, at the Patent Office library, and for this reason are more readily searched there than elsewhere.

In addition to the foreign patents available at the Patent Office library, duplicate sets of patents of several foreign countries are accessible to the examiners in the examining divisions, classified the same as the United States patents, but may be there examined only with the examiner's permission.

The patents of some foreign countries are not available even at the Patent Office, particularly of those countries which do not publish their patents. Copies of such patents are usually obtainable only in manuscript form from the patent offices of these respective countries. Information regarding such patents may, however, be obtainable through the official Patent Office publications of each country. Thus, Canadian patents are not published, but certain of the patent claims are published in the *Patent Office Record*.

Frequently the same invention will be found patented in several different countries, and will be found abstracted or reviewed in the current literature. Again, the inventor may publish a full account of his work in addition to the particular part which he patents. Accordingly, when a patent is discovered which is of particular interest, it is sometimes profitable to see whether the same inventor has taken out patents in other countries, or has published other descriptions of his work at about the same time, from which still further information is obtainable.

If reference is found to foreign patents which were not published, or which are not available, it may nevertheless be possible to find a corresponding patent granted in another country, if there is any, or find further information about the particular patent or invention from the contemporaneous periodical literature.

OFFICIAL PUBLICATIONS RELATING TO PATENTS

United States. The official publication of the United States Patent Office is the *Official Gazette*, issued weekly. It contains an abstract of all patents granted each week, giving the title of the invention, the name of the inventor, the assignee if any, the date of filing and serial number of the application for patent, the classification of the patent (according to the Patent Office classification), one or more typical claims of the patent, and an illustrative figure of the drawings if the patent is accompanied by drawings. It also includes an index of patentees and of inventions, and a classified list of the patents, classified according to the Patent Office classification. The subscription is \$5 a year from the Superintendent of Documents, Government Printing Office, Washington.

Yearly indexes of United States patents and patentees

(including assignees) are also published under the title "Annual Report of the Commissioner of Patents." These annual indexes, during the last few years, also contain a classified list of the patents according to the Patent Office classification. These annual indexes are also obtainable from the Superintendent of Documents (price \$1).

Canada. The official publication of the Canadian Patent Office is the *Canadian Patent Office Record*. It is similar to the *Official Gazette* of the United States Patent Office. The annual subscription rate is \$4 from the Commissioner of Patents, Ottawa.

Great Britain. The official publication of the British Patent Office is the *Illustrated Official Journal*. It is published weekly and contains illustrated abstracts of all British patents, as well as indexes of applications filed and patents granted. This publication is obtainable from the Patent Office, London (subscription rate £3).

Germany. The official publication of the German Patent Office is the *Patentblatt*, published weekly, with a supplement *Auszüge aus den Patentschriften*, containing illustrated abstracts of German patents.

SUBSCRIPTIONS TO UNITED STATES PATENTS

By making a deposit with the Patent Office, it is possible to subscribe for one or more classes or sub-classes of United States patents and to obtain from week to week copies of the patents that are granted in such classes or sub-classes. In order to obtain patents relating to any particular subject, it is necessary to subscribe to such classes or sub-classes as contain patents relating thereto. It is not possible, for example, to subscribe for "all chemical patents," or all patents relating to the production of a particular chemical substance, but it is necessary to subscribe for specific classes or sub-classes according to the Patent Office classification. Subscriptions of this kind, therefore, may include many patents that are not of interest to the subscriber but which happen to be classified by the Patent Office in the same classes or sub-classes as patents in which he is interested. The minimum deposit required to enter a subscription is \$5. Inasmuch as the cost of patents is 10c. each, it is evident that the cost of the subscription, and the period of time which a given deposit will cover, will vary with the number of patents issued in the particular classes or sub-classes subscribed for. The deposit must, of course, be replenished from time to time to maintain the subscription in force.

OBTAINING COPIES OF UNITED STATES PATENTS

Copies of United States patents can be obtained from the Patent Office at Washington for 10c. each. For convenience in ordering patents and in remitting therefor, the Patent Office sells coupons, specially printed for the purpose, in books of one hundred coupons for \$10 and pads of twenty coupons for \$2. The use of these coupons requires merely the filling in on the coupon of the data of the patent and the address to which the patent is to be sent, and the forwarding of the coupon to the Patent Office. For ordering small numbers of patents from time to time the use of coupons is usually more satisfactory than the making of separate remittances with each order.

It not infrequently happens that United States patents cannot be obtained in printed form from the Patent Office, owing to the temporary exhaustion of the supply. Photographic copies of such patents can, however, be

obtained, either from the Patent Office or from some library that has copies of the patents and facilities for photographic reproduction.

OBTAINING COPIES OF FOREIGN PATENTS

While copies of foreign patents can be obtained by sending to the respective countries for them, this involves a considerable delay. A more expeditious way of obtaining copies of such patents is by ordering photostatic copies from the Patent Office at Washington, or from such libraries as contain them and have facilities for photographic reproduction. The patents of most foreign countries, in so far as such patents have been published, are available at the Patent Office at Washington, and photostatic copies of any such patents can be obtained. The cost of obtaining patents in this way depends upon the number of pages of the specification and the number of sheets of drawings. The charge by the Patent Office is 15c. a page for single pages and 25c. a page for double pages. An estimate of the cost of any particular patent or patents can be obtained from the Patent Office in advance of ordering them. By making a deposit with the Patent Office of \$25, with replenishment of the deposit as it becomes exhausted, such copies of foreign patents can be ordered and charged against the deposit account. Photostatic copies of United States patents (where the printed copies are exhausted) as well as of other publications in the Patent Office library can similarly be ordered and their cost charged against such a deposit.

The patents of some foreign countries are not published, and these patents are usually obtainable only in manuscript form, or in the form of photographic copies, from the Patent Office of the country in which they are granted. Canadian patents (which are not published) can thus be obtained from the Patent Office at Ottawa. Estimates of the cost of such patents will be furnished by the Canadian Patent Office upon request.

Where any large number of foreign patents are desired, and the delay of a few weeks in obtaining them is not of particular importance, they can usually be obtained at less expense by ordering them directly from the country of their origin.

OBTAINING COPIES OF PERIODICALS AND OTHER PUBLICATIONS

The obtaining of copies of articles appearing in periodicals and other publications has been very materially facilitated by the photographic processes of reproduction which have been installed in many of the leading libraries. These facilities are of special importance to investigators of the chemical literature, whose investigations frequently lead them to periodicals and other publications that are available only at certain libraries. They are also a great convenience in enabling the investigator to obtain copies of separate pages, or of articles from different periodicals, etc., in a form convenient for future reference and consideration. The cost of obtaining photographic copies varies somewhat with different libraries, but is usually around 15c. to 25c. a page.

Among the libraries which thus furnish photostatic or photographic reproductions of periodicals and other publications are the Patent Office library at Washington, the John Crerar Library of Chicago, the Carnegie Library of Pittsburgh, and the Engineering Societies, Chemists' Club and Public Libraries of New York City.

IMPORTANCE OF PROVIDING BETTER FACILITIES FOR INVESTIGATING AND USING THE CHEMICAL LITERATURE

The importance of providing better facilities for making use of the chemical literature is well set forth in the following extract from the "Report of the Committee on Publication of Compendia of Chemical Literature, etc.," appearing in the *Journal of Industrial and Engineering Chemistry* for May, 1919, pages 415-417:

The committee recommends cordial and effective co-operation in suitable ways by the American Chemical Society and other American scientific and technological bodies with the efforts of the chemists of Great Britain to organize the work of publication in English of compendia of chemical literature and to encourage the production of chemical literature in English.

In presenting the whole problem of the organization of compendia, monographs, etc., in English by the British as well as by ourselves, the committee would urge that the question be considered from the point of view of national (cultural) importance as well as from that of scientific utility. The almost exclusive use of German compendia and monographs in all countries has given the German scientists an influence in foreign countries (from China to Argentina, Spain and Russia, and all lands between these countries) entirely out of proportion to their real share in scientific productiveness—leading to the migration of foreigners to Germany for their advanced studies, with resultant serious influences, political, commercial and cultural, in these countries. We must recall, too, that in their compendia and monographs, German chemists have been wont to ignore to a certain large extent, or to underrate, the work done in other countries, especially perhaps that done in the United States.

The compilation of compendia of chemical literature requires extensive investigation of the literature by the compilers. The production of monographs of value likewise requires investigation of the literature by the producers. Such investigations necessarily involve the use of library facilities, and must be made by investigators trained and experienced in making such investigations. Accordingly, if the compilation of compendia and the production of chemical literature in English are to become at all general, and if proper use and investigations of the literature are to be made in connection therewith, and by chemists generally in the practice of their profession, it is important for future American chemists to be trained properly in the use of the chemical literature and in the facilities for its investigation.

TRAINING IN THE USE OF CHEMICAL LITERATURE

Adequate training in the use of the chemical literature is not as general as it should be, nor does its importance seem to be generally recognized. The proper use and investigation of the chemical literature necessarily involves the use of library facilities and familiarity therewith, yet until recently we find no text-book or manual dealing with the subject comparable to the many laboratory manuals which deal with the use of laboratory facilities.

A discussion of the extent to which training in the use of chemical literature is given in a number of American technical schools and universities is given in an excellent paper on "Chemical Literature and Its Use," by Miss Marion E. Sparks of the University of Illinois, appearing in *Science* for April 19, 1918, pages 377-381. In this paper Miss Sparks also describes the Journal-Library Course given to students in the chemical and chemical engineering courses at the University of Illinois. This paper is much less complete, however, than the lecture notes used in the course, which outline the entire subject in a comprehensive manner. These lec-

ture notes were published by Miss Sparks in pamphlet form in 1919. The first edition is already exhausted but a second edition will probably be published during the present year.

There is likewise need of a more general appreciation, among American chemists and among American colleges, technical schools and universities, of the importance of proper use of the chemical literature, and of more general training in its use. "Library" courses, as well as "laboratory" courses, should be included in every college and university course in chemistry and chemical engineering.

Legal Notes

BY WELLINGTON GUSTIN

Process for Making Arsenate of Lead Is Held Valid —Growth of the Industry

In a suit on the Luther and Volck patent, No. 892,603, for a process for making arsenate of lead, the Circuit Court of Appeals of the United States has affirmed the lower courts' decision holding the patent not void for lack of invention. The California Spray Chemical Co. charged infringement of the process by the Toledo Rex Spray Co.

The process is carried out by combining lead oxide (litharge) suspended in water and arsenic acid in solution; the reaction being assisted by the cyclic action of the catalyzing agent—either acetic acid or nitric acid. The specification gives the formula or combining weights of lead oxide and arsenic acid, respectively, as varying from 1.938 to 2.9 parts of the lead oxide to one part of arsenic acid, according as ortho-arsenate or pyro-arsenate is desired. As shown by the specification, the weaker acid solution produces the ortho-arsenate, "with traces of pyro-arsenate of lead, lead salts of the catalyzer, and the catalyzer." The stronger acid solution (practically two parts of lead oxide and one part of arsenic acid) produces pyro-arsenate, "with traces of ortho-arsenate of lead, lead salts of the catalyzer, and the catalyzer." A varying of these proportions produces a corresponding variation in the acidity of the product. The preferable proportion of the catalyzing agent is given as "1 to 3 lb. of the catalyzer to 100 lb. of the lead oxide."

DEFENSE OF LACK OF INVENTION AND INSUFFICIENT DISCLOSURE

The defenses were that the patent was invalid and there was no infringement. It was contended that in view of the prior art there was lack of invention, especially if the patent was construed broadly enough to include defendant's process, and that the patent did not sufficiently disclose its process.

Regarding invention it was said that standard chemical authorities had taught that arsenate of lead could be obtained by the action of arsenic acid or nitrate of lead, by direct precipitation. Previous to the patent in suit the commercial method of making arsenate of lead was by combining either acetate of lead or nitrate of lead with arsenate of soda; the products of the respective reactions consisting of arsenate of lead, together with acetate or nitrate of soda, according as acetate or nitrate of lead was used. In neither the

general teaching nor the double decomposition process was there any catalytic or cyclic action involved.

However, back in 1866, Bell and Fell had been granted a patent, No. 59,901, for an improvement in the manufacture of white lead, by which sulphate of lead was produced by the direct action of nitric acid upon lead oxide (forming nitrate of lead), to which product was added sulphuric acid and water, resulting in a lead sulphate. In this process the nitric acid acted as a catalyst or agent in liberating, from time to time, portions of the oxide of lead and converting the same into lead nitrate, which, by the action of the sulphuric acid, are immediately converted into lead sulphate, the constant repetition of this process until the whole mass of lead oxide is converted into lead sulphate constituting the so-called cyclic action. The patent also states that acetic acid may be used in place of nitric acid.

QUESTION OF INVENTION CONSIDERED

Therefore, the court said the presence or absence of invention in the patent in suit depended on whether at the time of Luther and Volck's application in 1907 it was within the expected skill of the chemist, knowing first that lead nitrate would react with arsenic acid to produce lead arsenate, and second that the Bell and Fell process converted lead oxide into sulphate of lead by the use of nitric acid as a catalyzer, to know further that arsenate of lead could be produced instead of sulphate by substituting arsenic acid for Bell and Fell's sulphuric acid. On these facts it would seem the presence of invention in the Luther and Volck patent was doubtful, says the court.

Arsenate of lead in combination with other substances has long been used in the paint and dye arts, but uncombined its sole use seems to have been as an insecticide. The insecticide art, however, involves not only chemistry but entomology, the live problem being to obtain a product such as will cover the foliage and fruit, and so result in killing the insect without killing or injuring either fruit or foliage. Climatic conditions and the degree of sensitiveness of both fruit and foliage are necessarily involved. The invention of the patent in suit came from a campaign for the extermination of the codling moth in California, conducted by the University of California.

A factory was established at Watsonville, Cal., for the manufacture upon a large scale of arsenate of lead in accordance with the formula of the patent. The process is shown to have substantial advantages over the process of the prior art, its new and especially distinguishing feature being the ability to control more positively and more readily the character of the arsenate (whether ortho or pyro), including the percentage of acidity. Evidence showed the process more readily and effectively produces superiority of product as respects smoothness, distribution and adhesiveness. The double decomposition process has been largely superseded by the process of the patent.

Beginning in March, 1916, licenses under the patent were issued to the two largest chemical corporations, perhaps the largest drug manufacturer, the largest dry color manufacturer, one of the largest paint manufacturers and one of the largest insecticide manufacturers in the United States—all except one operating upon substantial royalties, the remaining company paying an outright consideration of \$30,000, besides royalties.

It was said that while it may seem that it would naturally have occurred to one acquainted with the

Bell and Fell disclosure to try the substitution of arsenic acid for sulphuric acid in making arsenate of lead, the fact remains that in the forty years which elapsed no one tried that experiment. In the light of that fact and the further fact that mere analogy is not, in chemistry, usually so certain an index as in mechanics, the court could not say that it was within the expected skill of the chemist to know that Bell and Fell's process of making sulphate of lead was equally available for producing arsenate of lead by the mere substitution of arsenic acid for sulphuric acid. Further, the court said that the favorable public reception and commercial success of the process in suit removed whatever doubt might otherwise exist as to invention.

DISCLOSURE SUFFICIENT, DECLARES THE COURT

On the question of lack of sufficient disclosure in the patent to enable one skilled in the art to practice it, the court held that it was sufficient to enable one skilled in chemistry to practice the process; though conditions of temperature, quality of the ingredients used and perhaps other elements require care and to some extent experimentation to produce the best results (*Minerals Separation, Ltd., vs. Hyde*, 37 Sup. Ct., 82).

As the patent was construed it was found that defendant's process infringed it. It employed 2.2 parts of lead oxide to one part of arsenic acid, being thus between the minimum and maximum of the patent, and it employed 2.81 per cent of nitric acid as a catalyzer, which is between the minimum of 1 and the maximum of 3 per cent specified in the patent. The court said it was not important that defendant makes only a pyro-arsenate, or that plaintiff uses the word "ortho" as a trade mark, making its ortho-arsenate product more prominent than its pyro-arsenate. Use of the formula of the patent was enough to charge defendant.

Where Customs and Usages Were Part of Contract —Deliveries Explained by Showing Custom

Customs and usages implied in a contract came up in a Georgia case in which the Producers' Co. sued the Empire Cotton Oil Co. alleging breach of two written contracts for the sale of peanut products. Under terms of one of the contracts the products were to be delivered in March, 1918; under the other, delivery was to be made in April, 1918. The plaintiff alleged that both contracts were breached by the Empire company in failing to deliver on demand in July, 1918, and sued for damages accordingly.

It was alleged that there was a custom of usage of the trade among dealers in peanut products to the effect that when, under a contract of sale, such products were to be shipped during a named month in the year, and delivery was not demanded by the purchaser during that month, and there was likewise no tender of delivery by the seller, the time of delivery was automatically extended from month to month until either the purchaser made demand upon the seller for delivery or the seller tendered delivery to the purchaser.

The Court of Appeals reversed judgment in favor of the plaintiff. It said while the terms of a written contract cannot be varied by a contemporaneous oral agreement, yet it is permissible to show the existence of a custom of the trade or business, not at variance with such terms, concerning which the contract was made, which is of such universal practice as to justify the conclusion that the custom became a part of the contract.

Effects of Metallic Structure Upon Properties

The Disposition, Amount and Nature of the Various Constituents of a Metallic Alloy Have a Great Effect Upon the Mechanical Properties of the Substance and Its Resistance to Corrosion, Especially in Strong Electrolytes

By HENRY S. RAWDON
Physicist, Bureau of Standards

THE ultimate aim of any metallographic examination is to show in what manner and to what extent the characteristics of the material, particularly the mechanical properties, are dependent upon the particular features characterizing the structure of the metal under observation. To discuss this phase of the subject, even in a manner only approximately complete, is manifestly impossible in small limits. Only a few of the most obvious effects of structure upon the properties will be mentioned.

MECHANICAL PROPERTIES AS AFFECTED BY STRUCTURE

It must be borne in mind in a discussion of this subject that the mechanical properties of any material, as expressed numerically, are more or less dependent upon the method of determination used—for example, size and shape of test specimen, rate at which the stress is applied, etc. The structural features of the material are closely related to the mechanical properties, this relationship of course being much more apparent in the case of the grosser or macroscopic features than for the very minute characteristics, as will be evident in the following examples which are discussed. The previous treatment, mechanical as well as thermal, also affects the mechanical properties, although in this case it may be contended that the structural effects caused by the previous treatments are largely, if not entirely, responsible for the changes noted.

HARD AND SOFT CONSTITUENTS

Many of the alloys most useful from the industrial standpoint consist of two or more constituents which vary quite widely in their characteristics. One of the constituents is often relatively very soft and ductile, while a second is hard and brittle. Such a condition occurs in steels, in aluminum casting alloys, and in

bronzes, particularly those for bearing purposes. The softer constituent gives the required ductility, while stiffness and strength are contributed by the harder one which is disseminated throughout the soft matrix. The relative proportions of the two determine the properties of alloys of the same general series which differ among themselves in their percentage composition.

Fig. 1 shows a specimen of cast zinc-bronze (approximately 88 per cent copper, 10 tin and 2 zinc) which was stressed in tension until fracture occurred. The soft ductile copper-rich matrix easily adapts itself to the applied loading, the hard brittle tin-rich constituent is shattered and broken, as shown, when stressed sufficiently. Similar cases may be noted in other alloys such as an aluminum casting alloy containing Cu 1.8 per cent, Mg 1.7 per cent and Mn 1.2 per cent. The hard constituent separating from such an alloy, consisting of a compound of aluminum and copper (CuAl_2), is sufficient in amount to form a continuous network throughout the alloy. The course or path of the fracture of a test specimen is determined by this network; thus the results of a tension test of such a material depend primarily upon the amount and the properties of this constituent.

SOFT DUCTILE CONSTITUENTS

Copper and lead do not alloy with each other in the sense that most metals do; neither solid solutions nor definite compounds of the two are formed. An "alloy" of these metals consists only of a mechanical mixture of the two metals, the intimacy of the mix depending largely upon the care used in preparation and the skill of the operator. The "alloy" may be considered, for convenience, as a copper sponge, the interstices of which are filled with globules of lead.

Although both copper and lead, when reasonably pure, are highly ductile, the mixture of the two behaves in a rather anomalous manner when tested. The behavior of the material when stressed in tension is somewhat as might be expected. It is somewhat ductile, but is decidedly inferior to metallic copper in its properties. Thus a tension test of an alloy consisting essentially of 40 per cent lead and 60 per cent copper gave the following results: Ultimate strength in tension, 10,650 lb. per sq.in.; elongation in 2 in., 8.5 per cent, and reduction of area, 7.5 per cent. The continuity of the copper matrix is so broken up and weakened by the inclosed globules of lead—which of course are of very low tensile strength—that the resulting tensile properties are correspondingly lowered. The properties measured are essentially those of the copper sponge and the properties of any particular specimen are inferior to those of a specimen containing the same amount of copper in the form of a solid, but smaller, rod.

FIG. 1. CAST ZINC-BRONZE PULLED AT RIGHT ANGLES TO CRACKS IN BRITTLE CONSTITUENT. $\times 250$
Etched with concentrated NH_4OH

Published by Permission of the Director, Bureau of Standards.

FIG. 2. Cu 60, Pb 40
BROKEN IN COM-
PRESSION. × 1

The appearance of the fractured specimen of the "alloy" when tested in compression is shown in Fig. 2. Although each of the two constituents is decidedly ductile under compression, the mixture of the two behaves in a manner characteristic of a brittle material. Instead of flattening to any appreciable extent the specimen shears in a manner such as is expected, for example, in cast iron. The inclosed globules of the lead undoubtedly contribute largely to the failure of the specimen in the manner shown by their action as a "lubricant." The ultimate strength in compression of lead is very much lower than that of copper; thus the lead yields under the applied loading and "flows" long before the copper is stressed to a degree which would cause appreciable deformation.

ORIENTATION OF TEST SPECIMEN

It is known that the mechanical working which is necessary for forming a metal after casting affects the structure to a very marked extent. The worked material has a more or less "fibrous" structure depending largely upon variations in composition across a section of the ingot used and particularly upon the various inclusions within the metal. After the working of the metal these are arranged in rather definite lines the course of which is determined by the shaping of the particular piece. It is evident that the mechanical properties, when measured across a laminated or fibrous material, will be quite different from those of the same material the test specimen of which was cut parallel to the course of the fibers. In the latter case—which covers by far the greater majority of the test specimens used in industrial testing—the mechanical properties are not seriously affected. It is only when it is specified, as is done for example in gun forgings, that the test specimen shall be cut transversely to the direction of working that the effect is marked. Fig. 3 shows the appearance of a specimen of gun steel (carbon 0.48, manganese 0.76, nickel 2.85, sulphur 0.02, phosphorus 0.02), broken in tension, the following results being obtained: Yield point (by divider method), 79,000 lb. per sq.in.; ultimate strength, 83,000 lb. per sq.in.; reduction of area, 3.5 per cent; elongation in 2 in., 3.5 per cent. The

very marked banded structure of the material which macroscopic examination (Fig. 4) showed was caused by threads of inclusions is unquestionably the reason for the very low ductility shown by the material. From the microstructure of this material (Fig. 5) one has reason to expect that considerable ductility would be shown. In Table I are summarized the results obtained by testing duplicate transverse and longitudinal specimens

of the same material in tension. The metal chosen was a type of defective steel encountered particularly in gun forgings, which has been designated as "flaky steel" of a composition very similar to that given above. Agreement among metallurgists as to the origin of these defects, "flakes," has not yet been reached. Defective material of the type used when tested in the ordinary manner shows apparently very superior properties, particularly in ductility. However, when a specimen cut transversely from the material is tested,

FIG. 6. MICROSTRUCTURE OF CAST ZINC-BRONZE AT FRACTURE. × 3
Etched with alcoholic ferric chloride.

it behaves very differently and breaks with practically no ductility. The elastic properties are not seriously affected, however, even when the internal defects are sufficient to reduce the ultimate strength of the material to approximately only 50 per cent of the normal value. When such material is subjected to some of the dynamic methods of testing, impact, fatigue, etc., the difference in the results obtained for the transverse specimen is usually even more marked than the results given above for the tension test.

It has been suggested that the grain size of a metal has a pronounced effect upon many of the properties of a material. Coarsely grained metals are quite universally regarded with disfavor, although there appears to be no evidence at hand to demonstrate the unsuitability of such material for many purposes. The brittleness, usually attributed to large grain size, is not very well revealed by a tension test, at least as ordinarily carried out. Fig. 6 shows a section of a coarsely grained tension specimen of cast bronze, (88:10:2) broken in tension. Fracture is intracrystalline. The structure indicates that the mechanical properties were determined to a very large degree by the fact that the entire cross-sectional area at the point at which the fracture occurred comprised only a few large grains. There was nothing, however, to indicate this until the specimen was sectioned and its structure examined.

A shock or impact test reveals the effect of coarse grain in a much more striking manner. Fig. 7 shows the appearance of a specimen of low-carbon steel, after testing in a Fremont impact testing machine which showed exceptionally superior qualities. The microstructure of Fig. 8 suggests that the superior shock-

FIG. 7. FREMONT IMPACT ON TOUGH LOW-CARBON STEEL. $\times 1.5$

FIG. 8. MICROSTRUCTURE OF FIG. 7. $\times 100$
Etched with 2% HNO_3 in alcohol

resisting properties were undoubtedly produced by quenching the steel from a high temperature, probably above that of the A_3 transformation. Another piece of the same steel, which had evidently been overheated in annealing and which showed a coarsely polyhedral structure, broke off easily and squarely. The entire lack of ductility of the coarsely grained specimen as compared with the superior shock-resisting qualities of the same steel when properly treated affords striking evidence of the influence of grain size upon mechanical properties.

PHYSICAL STATE OF MICROSCOPIC CONSTITUENTS

The relative size, arrangement and method of distribution of the various constituents which make up the structure of an alloy bear a close relationship to the various properties of the alloy. This is best noted in a binary alloy—for example eutectoid carbon steel—different specimens of which have been subjected to various thermal treatments with the express purpose of producing the variations in the microstructural features suggested above. Precautions of course must be taken that no phase changes in the alloy occur and that it is

in stable equilibrium throughout, the differences produced in the structure being physical ones only.

Considerable investigational work has been done to show how the mechanical properties of carbon steels, particularly those of eutectoid composition, vary with the physical state of the pearlite, the steel being in the softened state throughout and the pearlite ranging from the lamellar type through various stages to the completely "divorced" or spheroidized condition. The work of Hanemann¹ and of Howe² illustrates this.

The influence of the physical state of the pearlite in steel upon the properties is well shown by a study of the magnetic characteristics of the same steel after various treatments.³ The various specimens of the steel (carbon 0.85 per cent, manganese 0.28) were cooled from the same temperature (800 deg. C.) at rates so chosen that the structure of the different specimens varied from a fine sorbitic condition to a "divorced" or spheroidized pearlite. Without discussing here the significance of the various properties revealed by the magnetic tests, it may be noted that the properties of the steel are affected to a marked degree by the changes which have been brought about in the physical state of the pearlite. Corresponding differences in the mechanical properties would also be found upon testing, although perhaps of not so great a magnitude as in the magnetic properties, since the magnetic tests are much more sensitive than the ordinary mechanical ones and often reveal changes which are detectable by almost no other means.

CHEMICAL PROPERTIES AS AFFECTED BY STRUCTURE

The chemical property of metals and alloys which is probably most important industrially is that designated by the rather loose term of "solubility." Upon this property depends the etching of metallographic speci-

FIG. 9

Variation in the solubility of 1% carbon steel in dilute sulphuric acid, after hardening and tempering to different temperatures. (Hanemann.)

mens, the coloring of metallic surfaces, the corrodibility of materials under service conditions, and often, by the selective corrosion of certain constituents, the complete deterioration of the entire alloy in service. This property of an alloy is often influenced to a marked degree by the structure.

³C. Nusbaum and W. L. Cheney. Bureau of Standards Sci. Paper 408 (1921).

SOLUBILITY OF TEMPERED STEELS

It is quite well recognized that the solubility of steel varies considerably according to the heat-treatment which it has received. Fig. 9 illustrates this variation of solubility according to treatment,⁴ which may be well shown in the following manner: Harden a rod of high-carbon steel (approximately 1 per cent carbon) by quenching in water from a temperature of 765 deg. C. and then differentially temper it by heating one end to approximately 850 deg. C. while the other is kept cool with water. Thus the rod is tempered at different points along its length at all temperatures between the two extremes. When immersed in dilute sulphuric acid (20 per cent solution) for a day the acid will eat into the rod at different rates, forming a neck close to the reheated end.

Considerable attention has been given to this property of tempered steels by foreign metallurgists, and it has been shown, as is illustrated by Fig. 9, that the rate of solubility can be used as an indication of the tempering a specimen of steel has received. Maximum solubility corresponds to a tempering at 400 deg. C. A special

FIG. 10

Microstructure of Muntz metal showing the two constituents α and β . $\times 500$. Etched with ammonium hydroxide and hydrogen peroxide.

name, Osmondite, has been given to steel in this particular condition on account of its characteristic properties.

Thus it is evident that the rate of solution is profoundly affected by the structure of the steel. In the form of the solid solution the material is the least soluble; as the degree of tempering is increased and the carbide held in solid solution is progressively precipitated, the rate progressively increases. The maximum solubility occurs in the troostitic steel after the simple solid solution has been changed by tempering into a state of agglomeration resembling that of an emulsion. The material in this condition is not resolvable under the microscope into its constituent parts. As the tempering is continued, progressively higher temperatures being used, the ultramicroscopic particles increase in size until finally the ordinary microscopic examination reveals them. This increase in the size of particles of the constituents is accompanied by a decreased solubility, although the fully annealed specimen is somewhat more soluble than is the material in its initial or fully hardened state.

CORROSION

This term when strictly used refers to the tendency of metals to revert to the stable form in which they

⁴H. Hanemann, "Einführung in die Metallographie und Wärmebehandlung," p. 87.

FIG. 11

Microstructure of a corroded sheet of Muntz metal after 7 years exposure in sea water. $\times 500$. Etched with ammonium hydroxide and oxidized in the air.

occur in nature—that is, the oxide. The subject is so broad and the contributing causes so many and so varied that considerable differences of opinion are held as to the mechanism by which the process of corrosion is brought about. Only a brief mention will be made here of how structural features aid in the process.

In general the corrosive attack of a metal is more pronounced in the direction of the "fibers" than across them. This is most marked in case of accelerated corrosion by exposure to sea air, sea water or similar conditions and is found in all types of readily corrodible alloys if in the wrought state. This may be attributed largely to the mechanical effect of inclusion streaks by affording lodgment for moisture so that the attack at such points is accelerated and access to the interior more readily gained along the line of the inclusion. Similar instances have been noted in wrought aluminum alloys in which it appears that the difference in the electrochemical properties of streaks of the metal in various

FIG. 12. FRAGILE CONDITION OF SHEET OF FIG. 11

stages of cold-working is responsible in a large degree for the fibrous appearance of the corroded ends of wrought rods.

Brass of the type termed Muntz metal, approximately 60 per cent copper and 40 per cent zinc, exemplifies well the specific effect of a metallographic constituent upon corrosion. Such a brass has a duplex structure, as is shown in Fig. 10, the α constituent being much richer in copper than the β . The zinc-rich constituent is quite readily attacked by sea water, the difference in the electrochemical potential of the two being a contributing factor. The zinc from the β is leached out and a spongy mass of "copper" remains filling the spaces previously

occupied by the β . (Fig. 11.) Thus the alloy is converted into a weak brittle mass consisting of a "sponge" of the more or less attacked α constituent and the pulverulent material resulting the disintegration of the β . Material of this kind in the form of sheets often becomes so brittle that it can be readily broken into small fragments in the fingers. (Fig. 12.)

A soft ductile metal like lead may under some conditions of accelerated corrosion become so brittle that it can be crumbled to powder in the fingers. This is most apt to occur if the lead is somewhat impure. Each grain, however, may retain its initial ductility and other characteristic properties of lead. The corrosive attack of the metal in one case studied^{*} was essentially intercrystalline in character, due in all probability largely to the impurity contained by the metal (1.09 per cent tin), although it was shown that lead of exceptionably high purity (99.99 per cent) is subject to intercrystalline brittleness under certain conditions. In lead cable sheaths the tin and other impurities present exist as constituents of a eutectic surrounding the crystals of lead; thus the corrosive attack will be localized to a large extent and the metal as a whole will show "intercrystalline brittleness."

The Manufacture of Arsenic Trioxide*

BY GEORGE VIE

THE manufacture of arsenic trioxide comprises two distinct stages—namely, production of the crude trioxide and its refining. Each of these stages comprises several different operations.

The production of the crude trioxide necessitates drying of the ore, roasting, purification of the arsenic trioxide vapors obtained in the roasting and their condensation.

The refining of the trioxide necessitates washing, drying, distillation and condensation of the refined product.

TREATMENT OF THE ARSENIC ORES

The arsenical pyrite used in the manufacture of the arsenic trioxide is first crushed by jaw crushers and then ground in a rotary ball mill. The ground product is then washed and freed from foreign matter, and as this product contains about 25 per cent moisture it is necessary to dry it before it is sent to the roasting furnaces. Formerly the drying was done at the top of the roasting furnaces by the waste heat, but this method had the disadvantage of cooling the furnace to an appreciable degree and thus reduced the roasting efficiency. At present the drying is done in mechanical driers (Fig. 1), which consist of an oven *A* into which the wet product coming from the washery in cars *B* is fed and conveyed by a screw conveyor *C* rotating at a given speed so as to keep the product in a loose state and convey the dried material to the outlet *D* leading to a bucket elevator. The oven is heated by a furnace *F*. By the use of this drying arrangement no dust fills the building and the steam is carried away through hoods and chimneys.

ROASTING OF ARSENICAL PYRITES

The arsenical pyrites properly ground and dried are conveyed by a bucket elevator to the charging hopper of the roasting furnaces. The roasting operation is sim-

ilar to that used in roasting copper and iron pyrites. Hand-rabbled furnaces of the Maletra type are now entirely replaced by mechanically rabbled furnaces, thus reducing the manual labor cost and the dangers of poisoning. The furnace used is of the vertical type, made of sheet iron lined internally with refractory material and externally with insulating material. The

FIG. 1. MECHANICAL DRIER

dimensions of the furnace are from 6 to 10 m. high and from 3 to 5 m. in diameter. A centrally located vertical shaft provided with rabbles rotates at a given speed. The dried pyrite enters the furnace at the top. A series of annular slabs of 10 cm. thickness with plane upper surfaces and curved bottom surface are placed in the interior of the furnace. Each slab is provided with openings for the charging of the pyrite and for the upward circulation of the arsenic trioxide vapors. The lower part of the furnace is fitted to receive the roasted pyrites, which now contain only a negligible proportion of arsenic. The shaft and rabbles are hollow and cooled by a cold air current supplied by a ventilator. This air current provides also the needed oxygen for the oxidation of the ore and facilitates the escape of the arsenic trioxide as soon as formed.

The oxidation takes place according to the equation

Peep holes in the furnace walls located at the levels of the rabbles permit the easy inspection of the operation of the furnace and of the rabbling mechanism.

PURIFICATION OF THE ARSENIC TRIOXIDE VAPORS

During the roasting process the material is continuously being ground by the rotation movement of the rabbles, so that although the rotation is usually only 5 r.p.m., sufficient finely pulverized pyrite is carried along by the vapors to discolor the final product. It is therefore necessary to separate these solid particles before the vapors reach the condensing chambers. This is done by the use of a dust separator placed at the furnace vapor outlet. This separator consists of an insulated chamber containing two fine-mesh rotating cylindrical screens through which the vapors have to pass. A large part of the dust is retained by the first screen and the vapor passing through the second screen is practically free of solid particles. The cylinders rotate at a speed of 2 r.p.m. The screens are kept clean by two cylindrical drums provided with metallic brushes which rotate in a direction opposite to that of

*From *L'Industrie Chimique*, December, 1920, pp. 426-429.

^{*}H. S. Rawdon, "Intercrystalline Brittleness of Lead," Bureau of Standards Sci. Paper 377 (1920).

the screens. The brushing is very efficient and the screens are always clean and offer very little resistance to the passage of the vapors.

CONDENSATION OF THE ARSENIC TRIOXIDE VAPORS

The purified vapors are drawn by a suction fan into a series of sheet lead chambers, Fig. 2. A very slight vacuum is maintained in the roasting furnace. To overcome the resistance offered to the vapors by the purifier and pipe lines the fan has to produce a vacuum of from 60 to 80 mm. of water.

The condensing chambers are separated into equal parts by vertical baffle plates, thus increasing the condensing surfaces. These baffle plates are of sheet lead,

FIG. 2. CONDENSING CHAMBERS

the same as the chamber walls. The use of sheet lead is necessary because SO_2 from the roasting furnace is carried over into the chamber and would soon destroy any other metal lining and baffles.

About a third of the height of the chamber is in the form of a truncated cone. Rapid condensation is facilitated by the use of sprays of cold water. The bottoms of the chambers are connected to a manifold conduit leading the condensed milky product into a vat provided with agitator to mix the product before it is sent to the filtering room.

The chamber nearest to the fan is not provided with water sprays, so that only dry gas passes the fan. The thoroughness of the condensing operation can be judged by the color of the gases leaving the fan. If they are whitish, it indicates that the condensation is not complete and that heavier water spraying is required.

FILTRATION

The condensed milky product is filtered in a specially constructed filter. This filter consists of a shallow tank, 4 m. long, provided with a false bottom spaced 20 cm. above the fixed bottom. The perforated false bottom is covered with filter cloth. The filtration is facilitated by continuous stirring with a revolving helicoidal propeller, the helices of which reach within a few centimeters of the filter cloth. This propeller will serve also to convey the partly dried product to the final drying compartments.

When the tank is filled with the milky condensate pumps of 13 cu.m. per hour capacity evacuate the space between the two bottoms and the greater part of the water is soon filtered out.

There are a series of such tanks, and each tank has its own vacuum pump. When the contents of a tank have been partly freed of the water the cake is somewhat dried by the circulation of a strong current of air. The cracks forming in the drying cake are kept well closed so as to avoid short circuiting of the air current. Experience has proved that by adding dry As_2O_3 to the partly dried mass the degree of dryness

which can be realized by this air-current drying is greatly increased, and it also prevents the helicoidal propeller from getting jammed by the sticky product.

DRYING

The preliminary air-dried product, which still contains from 20 to 25 per cent of moisture, is completely dried in a reverberatory furnace, or better still, in a horizontal rotary drier. This latter consists of a horizontal sheet-iron cylinder having about 10 sq.m. drying surface and rotates at a speed of 10 r.p.m.

The feeding to the drier is made by the helicoidal propeller and the sticking of the material to the sides of the cylinder is prevented by the use of a smooth porcelain lining. The drying temperature is below 180 deg. C., thus avoiding any distillation of arsenic trioxide and its subsequent loss. The resulting steam escapes to the atmosphere through a chimney placed above the outlet from the drier. The dried product is led to bucket elevators and conveyed to the refining department.

REFINING OF THE CRUDE ARSENIC TRIOXIDE

The refining of the crude arsenic trioxide involves the following operations: Distillation, condensation, filtration and drying.

The distillation of the dried crude arsenic trioxide can be carried out in different ways. Some plants still use fireclay retorts similar to those used for the manufacture of coal gas, but the charging of the retorts requires very difficult and long manipulation. The latest improvements for industrial arsenic trioxide distillation consists in the use of a furnace 3 to 4 m. in diameter and about 50 cm. deep made of pig iron. The cover is provided with openings for the inlet of the crude material brought to the hopper by bucket elevators and for the outlet of the vapors. An axial shaft provided with rabbling arms rotating with a speed of 5 r.p.m. serves to stir the material uniformly and avoid the sticking to the bottom. It has been found that 245 deg. C. is the most convenient distillation temperature. This type of furnace offers the advantages of fuel economy besides those of mechanical charging, rabbling and uniform distillation. Industrial average data have shown that about 70 kg. of coal is required per 100 kg. of refined arsenic trioxide.

The final condensation takes place in lead-lined wooden chambers in the form of inverted rectangular pyramids. Each chamber is divided into two compartments so as to increase the condensing area. About 3 kg. of trioxide is condensed per sq.m. of condensing area. The outlet from the condensing chambers leads to a coke-filled tower, in which the last traces of the trioxide are condensed by a continuous spray of water.

A porcelain screw conveyor operating in a trough connected to the bottoms of the condensing chambers removes the refined material to the packing department.

The finished product, As_2O_3 , is finely powdered, perfectly white and quite chemically pure, analyzing 99 per cent As_2O_3 .

Importation of Dyes and Dyestuffs Into Egypt

The amounts and values of dyes and dyestuffs (exclusive of natural and synthetic indigo) imported into Egypt for the first eight months of 1919 and 1920, respectively, were 104,700 and 189,400 lb., valued at \$98,000 and \$146,000. Values are converted into dollars at the normal rate of exchange (20.23 piasters = \$1).

Recovery of Potash Alum and Sulphur at Tonopah

Description of the Process and Plant Operated by the Western Chemicals, Inc., in the Recovery of Potash Alum and an Agricultural Grade of Sulphur by Extraction and Flotation

By LINDSAY DUNCAN
Consulting Engineer, San Francisco

ABOUT thirty-five miles west of Tonopah, Nev., and six miles south of the Tonopah & Goldfield R.R. there is a deposit containing potash alum and free sulphur. The deposit was first described by J. E. Spurr, although it had been previously prospected and located as a sulphur mine. The alum and sulphur occur together in thin stringers running throughout a mass of decomposed rhyolitic tuffs. More than 100,000 tons has already been blocked out, and the estimated probable tonnage is more than 1,000,000. The deposit is owned by the Western Chemicals, Inc., of Tonopah, Nev., and a plant has recently been put in operation for the recovery of the alum and sulphur.

A typical analysis of the run-of-mine ore is given in Table I. With the exception of a very small amount of calcium sulphate, the alum is the only soluble sub-

TABLE I. ANALYSIS OF RUN-OF-MINE ORE

stance in the ore. Potash alum is very much more soluble in hot than in cold water, while the solubility of the calcium sulphate does not vary with the temperature. It is therefore possible to recover the alum free from calcium sulphate by merely dissolving the ore in hot water and crystallizing the alum by cooling the solution, leaving the calcium salt in solution.

MATERIAL USED IN THE PLANT DESIGN AND PROCESS OF TREATMENT

In designing the plant considerable difficulty was caused by the fact that the hot saturated alum solutions would attack most of the materials commonly used in construction. Aluminum, copper, iron, tin and nickel in

various compositions were tried and found unsuitable and as finally constructed wood, rubber, chemical and antimonial lead were the only substances allowed to come in contact with the alum solutions after leaving the ball mill, and the mill is lined with silex blocks set in water glass and sand and Danish flint pebbles are used for grinding.

The method of treatment consists in first dry-crushing the ore to $\frac{3}{4}$ in. by a jaw crusher and then grinding to 80 to 100 mesh in a 5 x 14-ft. pebble mill, the grinding being done in warm solution from the first cone.

The pulp from the pebble mill is delivered to the dissolving section of the plant by an air lift. The dissolving section consists of five 10 x 8-ft. propeller-type agitation tanks, five 5 ft. 6 in. Allen cones and five air lifts. The process is essentially that of continuous counter-current leaching in which the pulp is dewatered at each of the five stages. The agitator tanks are made of redwood, the propellers of antimonial lead and the propeller shafts are lead covered. All pipes leading to or from the tanks are of lead. The Allen cones are constructed of redwood and all metal parts are of antimonial lead. The air lifts are formed of redwood pipe; the tail pipe is a machine-banded stovepipe with a solid redwood plug in the bottom; the discharge pipe, which is exposed to the action of the solution on both sides, is solid bored. The air pipe is of lead where submerged.

FLOW SHEET OF THE PLANT OPERATION

Referring to the flow sheet (Fig. 4), the pulp leaving the ball mill flows to No. 1 air lift and is discharged to No. 1 agitator. It then flows to No. 1 Allen cone, where it is dewatered; the spigot product drops to No. 2 air lift, which in turn discharges to No. 2 agitator, the cycle of operations being repeated in each succeeding unit. The spigot product of the fifth cone, which contains less than 1 per cent of soluble alum, is delivered to the flotation unit.

The pulp remains in each agitator about three hours,

FIG. 1. POTASH ALUM-SULPHUR DEPOSIT

FIG. 2. FACE CUT INTO ORE

and as about four hours is required to dissolve completely the alum from the pulp, under operating conditions, it is evident that the solution of the alum is complete before the pulp leaves the second agitator. The function of the last three agitators and cones is simply that of washing the pulp and replacing the alum-laden solution with fresh water. Fresh hot make-up water is admitted to the fifth agitator and together with the agitated pulp goes to the fifth cone. The overflow solution from the fifth cone flows to the fourth air lift; a portion is, however, returned to the fifth air lift to maintain the proper dilution of the pulp. The solution is advanced in this manner progressively from the fifth to the first agitator, increasing in alum content. The third, fourth and fifth agitators accomplish the washing and the solution takes place in the first two. The overflow solution from the first Allen cone is divided into two portions, part going to the crystallizing vats, the remainder to the pebble mill, from which it returns to the first air lift with the freshly ground ore.

Live steam is used to heat the solutions and is admitted to the vortex of the agitators, where it is drawn down into and distributed throughout the agitated liquid by the propeller. Thermostatic valves control the temperature of the solution in the agitators at 85 deg. C. Lead-covered bulbs governing the steam valves are inserted through the sides of the agitator tanks.

The portion of the solution overflowing from No. 1 Allen cone, which is not used in the pebble mill, is forced by a 1-in. lead-lined centrifugal pump through Sperry filter presses. The presses have wooden plates, and woolen filter cloths are used. Each filter has a filtering area of 100 sq.ft. and a cake capacity of 5 cu.ft. The two filters are set in parallel and are valved with lead-lined stopcocks so that either press can be cut out for cleaning without interfering with the operation of the other. The filters remove colloidal material that may be present in the overflow from the first Allen cone, and the filter cake is delivered to the flotation cell feed box.

The filtrate flows to one or more of the four 29 x 6-ft. crystallizing tanks. After the alum has crystallized

FIG. 3. PLANT OF WESTERN CHEMICALS, INC.

FIG. 4. FLOW SHEET OF PROCESS

from the solution in a tank the mother-liquor is returned to No. 3 agitator and the tank is again filled with pregnant solution. When a tank is finally filled with alum crystals the motor-liquor is completely drained off. The crystals are removed through an acid-proof wooden gate valve in the bottom of the tank, fall into cars and are trammed to the drying shed.

SULPHUR RECOVERY

The underflow from No. 5 Allen cone, which has been practically denuded of alum and contains approximately 30 per cent of moisture, is delivered by launder to a feed box for the flotation cell, where it is mixed with the return water from the flotation cell. Hot make-up water is added at this point, as it has been found that a better recovery of the sulphur and a higher grade of concentrate is obtained by the use of hot water in the flotation cell. From the feed box the pulp flows directly to a six-compartment Colburn flotation cell which has a capacity of about 2½ tons of feed per hour. The sulphur concentrates are pumped to a 6 x 6-ft. Oliver filter and the filter cake is trammed to the drying shed. The filtrate flows back to the feed box. The tailing product is pumped to a 16-ft. Dorr thickener, the underflow from the thickener is filtered by a 6 x 6-ft. Oliver filter and the overflow returns to the feed box. The filter cake is trammed to a dump and the filtrate flows to the feed box. These steps are necessary to conserve water, which is very difficult to obtain in a Nevada desert. The sulphur recovery is from 85 to 90 per cent and the grade of the concentrate from 80 to 85 per cent. The impurity is almost entirely silica. The product is particularly desirable for dusting vines.

CAPACITY OF THE PLANT

The capacity of the entire plant is governed by the mechanical loss of alum which it is economical to allow. A loss of 5 per cent has been decided upon and under these conditions the plant will produce about ten tons of c.p. alum and ten tons of 85 per cent sulphur concentrates per day.

The plant was designed and constructed by Duncan & Lindley, Mills Bldg., San Francisco. The chemistry of the process was reported upon by Dr. Merle Randall and the geology of the deposit by Dr. A. C. Lawson, both of the University of California.

Silver Peak, Nev.

Cost of Fixed Nitrogen in Norway

BY T. C. HAGEMANN*

THE object of the present article is not to make an accurate calculation of the cost of construction and working expenses of a plant for the manufacture of nitrates by the electrical oxidation of air, but, taking into consideration the market price of the products, to show that this process is profitable in Norway. If one intended to do so, it would be absolutely necessary to know the location of the plant in contemplation and the exact cost of materials, machines and apparatus, besides local prices of power, raw materials and wages.

STEPS IN THE PROCESS

Let us first outline the steps in an arc-process plant.

The air to be treated is let into a chamber, where it passes through an electrical arc, which by some artificial means is given an increased area in order to heat the air so intensely that a part of the nitrogen burns—that is, combines with the oxygen and forms NO .

The nitrous gas, which at the outlet of the furnace has a temperature of about 1,000 deg. C., passes first through a steam boiler, where it gives up the greater part of its heat to the water in the boiler, thus producing steam of a convenient pressure and temperature. The further cooling of the gas (from about 200 deg. C. to about 40 deg. C.) occurs in coolers fitted with tubes of aluminum, this part of the heat being lost with the cooling water.

During the following stay of about one minute in the oxidation chamber the nitrous oxide has time to combine with one more molecule of oxygen and forms NO_2 .

The gas is now fit for absorption and accordingly passes through a series of towers of granite—generally four—filled with broken quartz. On the top of the fourth tower water enters as a spray and runs out at the bottom in form of weak nitric acid. A portion of this acid is forced back to the top of the same tower, while the rest is forced to the top of the third tower, and so on. At the bottom of the first tower it meets the fresh gases from the oxidation chamber, and a weak nitric acid containing about 30 per cent HNO_3 by volume is produced.

CONVERSION TO CALCIUM NITRATE OR SODIUM NITRITE

This acid is not suitable for transportation, and must first be concentrated to the strength of 96 to 98 per cent HNO_3 , in which form it can be transported without any difficulty in containers made of 98 per cent aluminum; or it can be neutralized with ammonia to form ammonium nitrate or with calcium hydrate to form calcium nitrate ("Norwegian saltpeter").

During the war there was a great demand for ammonium nitrate, but now, in peace time, preference is given to the more pacific material calcium nitrate.

In this case, we allow the acid to pass through open towers, filled with limestone, and afterward we destroy the small amount of remaining acid in the solution with slaked lime. We then remove a part of the water content in evaporators fitted with copper steam coils, until the solution contains 13 per cent N, utilizing steam from the boilers in which we have cooled our gases. We now pass the solution into flat pans or in a more improved apparatus, allow it to solidify on rotating water-cooled drums. The crude lumps from the pans,

or from the surface of the drums, are broken up and then packed into barrels, ready for marketing. By the process described above, we can utilize about 80 per cent of the nitrous oxide content of the gases.

In order to recover an additional 15 per cent, the gas from the fourth "acid tower" is led into a tower, which may be made of iron, filled with broken quartz, and through which is pumped soda lye, until the solution at the bottom of the tower contains practically pure sodium nitrite.

Owing to the fact that the market for this very valuable product, NaNO_2 , is rather limited, we convert it to the less valuable product sodium nitrate by means of nitric acid. The solution is then evaporated, crystallized in flat pans or, more rationally, in finishers, fitted with salt boxes, centrifuged, dried with hot air and packed into sacks ready for market.

ESTIMATED YIELD

Concerning the quantity of the finished products, we are in any case safe, if we figure on a yield of 540 kg. HNO_3 (calculated at 100 per cent per kw.-yr., or 62½ g. per kw.-hr.). For a medium-sized factory, say of 40,000 kw., the amount, after having subtracted the power for working the auxiliary machinery, will be about 20,000 tons HNO_3 , equivalent to 4,500 tons N, in the form of 29,000 tons Norwegian saltpeter with 13 per cent N, and 4,400 tons sodium nitrate with 16.5 per cent N.

Of raw materials there will be required 15,000 tons limestone, 500 tons lime and 2,500 tons soda.

For the economical calculation I prefer to figure in Norwegian kroner, being most familiar with that coinage. (1 kr. normal exchange or parity = \$0.268, at present market = \$0.18.)

The market price of the nitrogen in the above-mentioned products is about 3,000 kr. per ton. Total selling price for 4,500 tons is 13,500,000 kr.

Approximate running expenses are:

	Kroner
Power, 40,000 kw. @ 100 kr.....	4,000,000
Administration and wages.....	1,500,000
Raw and other materials.....	1,100,000
Packing	1,000,000
Sundries	400,000

Total 8,000,000

Balance: 13,500,000 kr. — 8,000,000 kr. = 5,500,000 kr.

The investment is estimated to be about 20,000,000 kr., and taking 7½ per cent, or 1,500,000 kr., for amortization, the profit will be about 4,000,000 kr.

As will be seen from the above, the cost of power represents half of the total running expenses, and indeed, this item, together with the relative yield of the future, is of vital importance when considering the cost and returns of any one individual factory.

DEMAND FOR THE PRODUCT

During my stay in the United States two years ago I was told that the Norwegian saltpeter was not salable in large amounts, because it is not applicable to the manufacture of the mixed fertilizer demanded by American farmers. Afterward I saw the same statement made in the technical journals. The fact is, however, that this product, calcium nitrate, is exported from Norway in increasing amounts, and if the claim of the producers that this fertilizer, especially on lime-poor soil, is more valuable than other fertilizers, is proved to be correct, it seems likely that the American farmers will find it to their interest to use it.

*Consulting Engineer for the Nitrate Industry, Christiania, Norway.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Phenol-Aldehyde Condensation Products.—Condensation products are obtained by reaction of phenol or its homologues with formaldehyde in the presence of dilute sulphuric acid in the proportions of 500 volumes of phenol or its homologues, 450 to 550 volumes of 40 per cent formaldehyde, and 2 to 6 per cent by volume relatively to the phenol of dilute sulphuric acid made by mixing 20 volumes of acid of 1.84 sp.gr. with 80 volumes of water the reaction being effected at a temperature of 60 to 80 deg. C. After reaction and removal of water, the product is neutralized—e.g., by milk of lime—and the remaining water is removed by heating *in vacuo*. The product may be finally hardened by heating under pressure. (Br. Pat. 153,494; A. T. BIRKLEY, and F. E. BIRKLEY, Liversedge, Yorkshire. Jan. 19, 1921.)

Devulcanizing Rubber.—Vulcanized rubber is devulcanized by simultaneous treatment with a benzene hydrocarbon, such as 10 per cent of xylol or one of its homologues and a carbocyclic amido compound, such as 2½ per cent of aniline or one of its homologues in the presence of a substance capable of absorbing or combining with sulphur, such as a hydrate of an alkali metal. The treatment is conducted in a digester in which the temperature corresponds with a steam pressure of from 60 to 150 lb. per sq.in. (Br. Pat. 153,646; J. YOUNG and W. W. BENNER, Akron, Ohio. Jan. 19, 1921.)

Sodium Nitrate.—Sodium nitrate is obtained from its solutions by first separating a considerable proportion of the sulphates and chlorides present by concentration under an absolute pressure of 11 lb. per sq.in. until the temperature of 90 to 95 deg. C. is reached, and afterward concentrating the liquor at atmospheric or other pressure until the content of chloride (calculated as the sodium salt) is 75 to 80 g. per liter. The concentrated liquor is then cooled for the production of sodium nitrate crystals. The first stage of the concentration is effected in a vacuum evaporator,

consisting of a heater 3 and a separator 7 connected by circulating pipes 6, 9. The crystals of chlorides and sulphates that separate are discharged through a valve 11 into a settling tank 12 from which they are removed by conveyors, 17, 19. The crystals may be washed by liquor from the store tank 1. A pump 2 feeds liquor from the store tank 1 to the heater 3, and a pump 21 returns liquor from the settling tank 12 to the heater. The second stage of the concentration is effected in an intermittently-working evaporator consisting of a heater 23 and a separator 24 operating under a pressure such that the steam generated may be led by a pipe 4 to the heater 3 and used as a heating agent therein. The evaporator 23, 24 is filled by adjust-

ing a valve 22 so as to permit a portion of the liquor from the pump 21 to enter the heater 23. When the liquor has reached the prescribed concentration, the contents of the evaporator 23, 24 are discharged through a filter 29 and are pumped into a chamber 32 maintained under an absolute pressure of 12 to 13 lb. per sq.in., and are cooled to 70 to 75 deg. C. by evaporation under the reduced pressure. The liquor is then transferred to a rotary cooler 37, in which the sodium nitrate separates. (Br. Pat. 153,649; J. L. GRINGIONI, Valparaiso. Jan. 19, 1921.)

Heat-Treatment of Steel.—Steel, after being heated to above the critical temperature, is cooled in proximity to an electro-magnet so that when the critical temperature is reached and the steel regains its magnetic properties, the attraction of the electromagnet may be arranged to give an indication that this temperature has been reached and, if desired, to effect a stoppage of the cooling. In the figure a railway wheel tire *a* is shown suspended in a cooling bath by dogs *b* from a ring *c*; an electro-magnet *f* is suspended above the tire by a spring *e* of such a strength that when the tire is cooled to the critical temperature and becomes magnetic, the magnet *f* moves downward against the spring until the collar *i* on the rod *g* comes

into contact with the stop *h*. This movement gives a visual indication or may be arranged to operate a switch to start a crane which lifts the tire from the cooling bath. In a modification the tire is placed on a revolving table and is cooled by a spray. In this case, when the tire becomes magnetic the core of a solenoid is attracted against a spring. The movement of the core may be used as a visual indicator or may operate a device for shutting off the cooling spray. (Br. Pat. 153,756; C. P. SANBERG and J. C. W. HUMPHREY, both of London. Jan. 19, 1921.)

Phenol-Aldehyde Condensation Products.—A thin aqueous liquid condensation product is obtained by reaction of about 1,000 parts of carbolic acid, 1,000 parts of 40 per cent formaldehyde and 50 parts of sodium sulphite, at ordinary temperature for three to four days. The product can be applied directly for impregnating fibrous, etc., materials, which are subsequently dried, and hardened by heating under pressure—for example in the manufacture of friction blocks or pads or stair treads. Water-soluble dyes may be dissolved in the liquid to dye textile materials. (Br. Pat. 153,796; F. SCUDDER and R. PETTIGREW, Manchester. Jan. 19, 1921.)

Solidified Oil Composition.—Tung oil or Chinese wood oil is solidified by the action of haloid salts, particularly chlorides, uniformly disseminated through the oil. To secure this dissemination, the chlorides are first ground up with an indifferent oil, such as resin oil or linseed oil, or dissolved in an anhydrous organic solvent, and the liquid produced mixed with the tung oil. Suitable combinations of salts and solvents are anhydrous ferric chloride in anhydrous acetone, anhydrous aluminum chloride in anhydrous acetone, anhydrous stannic chloride in acetone, anhydrous zinc chloride in amyl acetate or alcohol, and antimony or bismuth chloride in acetone; the use of ferric bromide is also mentioned, and mixtures of various salts may be employed. Fuming chlorides, such as antimony chloride or stannic chloride may be dissolved in benzine or the like and mixed with an indifferent oil and the mixture added to the tung oil, or they may be changed into hydrated chlorides and dissolved in anhydrous solvent and used directly. Filling and coloring matters, fibrous or otherwise, may also be added; a number of suitable and unsuitable substances are mentioned. Rosin gums, ester gums, or other gums easily soluble in oil may be added to the tung oil, as may tung oil fatty acids. Either raw or blown tung oil may be employed, but oil that has been partly polymerized by heat is unsuitable. (Br. Pat. 153,942; B. SCOBEL, New York. Jan. 19, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Preliminary Program, Rochester Meeting, A.C.S.

While the full program for the spring meeting of the American Chemical Society, which will be held in Rochester, N. Y., April 26 to 29, has not been completed as this is written, some features of the program are known at this time. Senator Wadsworth of New York and Representative Longworth of Ohio have promised definitely to address the meeting and have been assigned places on the program of the opening day. On that day also E. C. Franklin will deliver his address on "Ammono Carbonic Acids."

GENERAL ARRANGEMENTS

Tuesday afternoon will be devoted to a general meeting which will be held in the large auditorium of Convention Hall. Alpha Chi Sigma will hold a banquet Tuesday evening at 6:30. Members desiring to attend this banquet should write to I. N. Hultman, Eastman Kodak Co., at their earliest convenience so that reservations can be made. Wednesday and Thursday will be devoted entirely to the presentation and discussion of papers. No excursions or other functions have been planned for these two days, so that there will be absolutely no interference with this part of the program, which is the most important side of the meeting. All divisions and sections can begin their meetings Wednesday morning simultaneously. The place of this meeting is Mechanics Institute and the rooms will be provided with modern projection apparatus and with communicating telephones so that members in other sections can be posted as to what is being done in various other sections. This scheme increases the time devoted to presentation and discussion of papers in all cases by at least one-half day and in many cases by a whole day. Wednesday evening will be given over to general addresses at Convention Hall. Thursday evening has been set aside for a good-fellowship meeting at the Bausch & Lomb Optical Co. Friday and Saturday will be devoted to excursions to the various industrial plants and laboratories in the city.

It is planned to charge a registration fee of \$1. This is in line with the action taken by the council at the fall meeting in Chicago. The money resulting from this registration will be used to defray necessary expenses incurred for arrangements of the meeting.

TENTATIVE DIVISIONAL PROGRAMS

The Division of Industrial and Engineering Chemistry will discuss drying under the guidance of Charles O. Lavett, the chairman of the drying symposium committee.

Division of Physical and Inorganic Chemistry will have a symposium on contact catalysis, over which W. D. Bancroft will preside. Among those who will present papers on that subject are A. F. Benton, R. M. Burns, R. F. Chambers, J. C. Frazer, C. H. Milligan, H. A. Neville, R. N. Pease, F. H. Pollard, E. Emmet Reid, F. L. Simons and H. S. Taylor.

The Division of Rubber Chemistry will discuss among other things a tentative draft of specifications for the analysis of rubber goods.

In view of the critical situation in the dye industry the meeting of the Division of Dye Chemistry is expected to be of unusual interest. The Division of Fertilizer Chemistry is the only division which will not have a group meeting at the Rochester convention.

LOCAL COMMITTEES IN CHARGE OF THE MEETING

The local committees and their chairmen who will be in charge of the meeting are as follows: Executive Committee, Frank W. Lovejoy, honorary chairman; J. Ernest Woodland, chairman; finance, Herbert Eisenhardt; enter-

tainment, Charles F. Hutchinson; registration and information, Harry A. Carpenter; program, Erle M. Billings; transportation, Charles Markus; hotels, Harry L. Gray; excursions, William Earle; arrangements, Donald B. Howe; college and fraternity dinners, and exhibits, Ivan N. Hultman; publicity, Benjamin V. Bush.

The council of the society will meet April 25 at Rochester.

Tariff Prospects

Since tariff legislation affects directly only 14 per cent of the population, while the internal revenue laws apply to practically 100 per cent, there is great political inducement for Congress to take up the revision of taxation ahead of the revision of the tariff. There is a substantial proportion of the membership in each house of Congress, however, that will demand immediate action on the tariff. They point to the chemical industries as affording the most clear-cut cases of the need for immediate protection from the increasing volume of imports.

It is not disputed generally that it would be very difficult at this time to write a permanent tariff measure. It is recognized that information is incomplete with regard to costs of production abroad. There is great uncertainty as to the trend of production costs even in the United States. Foreign exchange adds another element of uncertainty. There is very general support, however, for the proposed re-enactment of a revised Payne-Aldrich bill or of a measure in which the schedules would be more or less arbitrarily arrived at. Either plan, it is argued, would serve as stop-gap measures to apply only until the regular bill can be worked out later in the year.

In the event of the adoption of the Payne-Aldrich schedule to serve until the regular bill can be put into effect, it is pointed out that considerable revision must be had of the rates of duty fixed in that act on chemicals. Since that law was enacted in 1909 a real chemical industry has been developed in the United States. As a result it is contended that many articles now on the free list should bear a duty, while changed conditions require higher schedules on many items.

The duties prescribed by the Payne-Aldrich act on some of the more important chemicals are as follows: Ammonia, liquid anhydrous, 5c. per lb.; essential oils, 25 per cent; coal tar, dyes or colors, 30 per cent; preparations of coal tar, not colors or dyes, 20 per cent; benzene, toluene and naphthalene, free; glycerine, refined, 3c. per lb.; chromium colors, 4½c. per lb.; litharge, 2½c. per lb.; white lead, 3c. per lb.; zinc oxide (dry), 1c. per lb.; zinc chloride, 1c. per lb.; carbon, 20 per cent.

Plans for Mme. Curie's Visit

As a mark of respect to Mme. Curie the formal opening of the Cryogenic Laboratory of the Bureau of Mines will be postponed until the visit of the noted French scientist. Plans are being perfected for other features of Mme. Curie's entertainment, which will include a general reception, at which time all scientists residing in Washington will be given an opportunity to meet the distinguished visitor. The arrangements are in charge of Dr. Vernon Kellogg of the National Research Council.

Buenos Aires Exposition Delayed

The American National Exposition, Inc., which was planning an exposition of United States manufacturers for March 1, 1921, at Buenos Aires, has postponed the enterprise indefinitely due to business conditions in Argentina. The exposition will not be permanently abandoned, and a proposed new date is November and December of this year.

Butyl Alcohol and Acetone From Starch

At the March meeting of the Indiana Section of the American Chemical Society held at Indianapolis M. E. Nasmith, superintendent of the Commercial Solvents Corporation of Terre Haute, Ind., described in considerable detail the process of making acetone and butyl alcohol from starch.

DEVELOPMENT OF THE PROCESS

The fermentation of the hydrolyzed starch is done by an anaërobic spore-forming bacterium, *B. Granulobacter pectinovorum*. This microbe was supplied by Fernbach of the Pasteur Institute to some Englishmen who were interested in producing acetone and higher alcohols for the synthesis of isoprene. At the outbreak of the Great War Weitzman, who had been associated with Fernbach, offered the use of this fermentation process to the British government for the production of acetone needed in cordite manufacture.

When Colonel Gooderham tendered the use of his distillery in Toronto to them the British sent over a chemist and bacteriologist. The difficulties inherent in the adjustment of such a process to a large scale were gradually overcome, but it seemed desirable to have a works nearer the source of raw material, so a distillery was selected in the corn belt at Terre Haute.

When the United States entered the war an adjacent distillery in the same city was adapted to this process, getting well started just before the signing of the armistice. The two governments were in partnership in these two plants. The English sold great quantities of acetone, so there was little demand for that substance after the signing of the armistice, but there has been a real need for higher alcohols for solvent purposes.

This demand encouraged the formation of a syndicate to take over the first plant, which was operated from April, 1920, to the end of that year. At present it is not producing solvents, but many improvements to the process are being worked out.

PREPARING CORN FOR FERMENTATION

Almost any starchy substance may serve as raw material, but there must be sufficient nitrogenous material to give the organism a suitable ration. Of course, corn is the principal substance used and is not hurt even if it has been frostbitten. If the corn is too damp, it must be dried before being stored. The corn is broken in corrugated rollers called "breaks" so that the hulls and bran may be separated from the starch. The germs of the corn are left to supply the organism with necessary nitrogen. The corn meal is gradually fed into ten parts of boiling water with constant stirring. Then the pressure is increased to 70 lb. in 20 min. To overcome the tendency toward foaming of the pasty material when the pressure is released the large pipe leading upward from the cooker is provided with an expansion or blow-off tank to prevent any loss. The cooking brings the starch into a finely divided, more or less hydrolized condition which is suitable for fermentation. It also sterilizes the starch very thoroughly. The cooked material is then pumped through 5-in. pipes to the 50,000-gal. fermentation tanks. The greatest care must be exercised in sterilizing everything with which the material comes in contact—a very nice problem with such large units. Also very great care and nice adjustment have to be exercised in controlling the temperature of the mash as it reaches the tanks, since the range of activity of the organism is limited. A slight lowering of temperature will chill the bacteria so that it may take 24 hr. to recover, and again a slight elevation may kill them.

FERMENTATION

The technique of handling and developing the cultures of this bacteria has to be of a very high order. The test-tube cultures are inoculated into 1,200-c.c. Erlenmeyer flasks and after 24 hr. the emulsion breaks, leaving the beer below, in which there is often a slimy streak or "shroud." The Erlenmeyers are taken to the seed room and the culture is introduced into sterile mash in sterilized 5-gal. copper kettles provided with hand stirrers. From

these in due time the inoculated mash is run into the empty sterile fermentation tanks and the mash is next added. The tanks are provided with water seals so that the gases evolved, 60 per cent carbon monoxide to 40 per cent hydrogen by volume, can escape. More or less of the volatile solvents is apt to be lost during this evolution of gas. During 24 hr. 26 tons of carbon monoxide and 1,800 lb. of hydrogen are evolved from a tank, but no attempt is made at present to recover them.

During the fermentation the acidity increases to a maximum, after which it steadily falls off to a constant value. The formation of the solvents begins at this maximum point. It seems probable that there is reduction by the nascent hydrogen of some of the acids formed. If wild ferments have got in, the acidity keeps on rising till the special bacteria are all killed, so that practically no solvents are produced and the batch is wasted.

DISTILLATION

The solvents are removed from the mash by the usual method with suitable heat interchangers. The spent mash contains 3 to 3.5 per cent of solids, which when dried contain 40 to 45 per cent protein, making it valuable for fertilizer or cattle feed. It is an interesting fact that the mash coming out from this still has about double the acidity of the ingoing mash. The water solution of the solvents is pumped into a 20,000-gal. discontinuous still provided with a 30-section rectifying column.

After the removal of the acetone ethyl alcohol is obtained in the next fractions. Then comes the constant composition vapor of waterbutyl alcohol containing 68 per cent of the alcohol. On cooling, this separates into two layers, the upper one containing 88 per cent alcohol to 12 per cent water and the lower one 8 per cent alcohol to 92 per cent water. On separation, the lower layer is run back into distillate from the mash column still, while the upper layer is redistilled in a smaller still. The distillate is always richer in water than the residue, so that finally pure butyl alcohol is left in the still.

From 1 bu. of corn 9.5 to 10 lb. of solvent is obtained. The solvent is a mixture of 60 per cent acetone, 30 per cent ethyl alcohol and about 10 per cent butyl alcohol. There are also traces of amyl alcohols. Butyl alcohol makes a fine solvent for many materials like fine paints and varnishes and rubber. It also is made into esters. The capacity of the plant is 7 tons of solvents a day.

Surplus Brass Sold

Sale of 30,000,000 lb. of brass cartridge cases has been announced by the Director of Sales. The purchasers are: Chase Co., Inc., Waterbury, Conn.; Scovill Mfg. Co., Waterbury, and the Bridgeport Brass Co., Bridgeport, Conn. The price is to be determined by the market price at the time sales are made by these purchasers. The government is to receive 41½ per cent of the average market price for the copper content, plus 19½ per cent of the average market price for prime Western zinc for the month in which deliveries are made. Under this agreement the government will receive a greater return than would have been the case had it accepted the highest bid offered for the outright purchase of the material.

In addition the government has 6,000,000 lb. of cartridge cases still on its hands. This will be held available for sale at any time to brass mills and other consumers under the same general terms.

Oil and Gas Claims in Alberta

It is reported from Edmonton, Alta., that nineteen oil and gas claims, covering 6,000 acres of ground, have been filed with the Dominion government at Fort Smith since the beginning of the year. Practically the entire area in the vicinity of Pine Point, Great Slave Lake, has been staked. The ground has been staked under the old laws, allowing the filing of 320-acre claims, by parties who started for the district before the laws were suspended. The government agent was unable to say what effect the new laws, recently passed but which were made retroactive to the first of the year, will have on these claims.

Need for Fertilizer Grows Rapidly

As a result of the controversy in Congress over the development of Muscle Shoals a great deal of statistical material was gathered in regard to the fertilizer requirements of the country. Among the striking facts brought out was the great increase in the use of fertilizers in sections of the country other than the South. In South Dakota the consumption of fertilizer in 1918 increased 1,150 per cent as compared with the consumption in 1911. During the same period Minnesota's consumption increased 250 per cent. In Oklahoma the increase was 212 per cent, in Wisconsin 200 per cent, in Iowa 150 per cent, in Missouri 122 per cent, in Delaware 216 per cent, in Connecticut 200 per cent, in Oregon 100 per cent.

Wood Pulp Mill at Juneau, Alaska

Wood pulp is now being manufactured in Alaska near Juneau, in the Tongass National Forest. The first mill to be established in this territory has a capacity of twenty tons of pulp a day, but the available hydro-electric power is ample to increase the output to 250 tons. Spruce and hemlock will be ground for newsprint purposes and later the plant will be enlarged so as to manufacture paper.

In response to inquiries from prospective manufacturer's Forest Service officials have announced that an area of the Tongass National Forest containing 2,000,000,000 ft. of pulp-making timber would be placed on the market soon.

American Oil Chemists' Society

For a number of years the leading chemists in the cottonseed oil industry have been fraternally associated in the Society of Cotton Products Analysts. This organization primarily concerned itself with perfecting methods of analysis used in the cottonseed crushing and refining industry. It did for the edible oil trade what the Association of Official Agricultural Chemists does for the food industry; the Society for Testing Materials for the paint trade; and the Leather Chemists' Association for the leather and tanning industry. Certain specific qualifications as to membership limited it in numbers to those highly specialized but insured a large amount of important investigational work. The great war drew this country into a large international trade in several of the vegetable oils which became keen competitors of cotton oil. This caused a commensurate widening of the society's interest, with the result that at the annual meeting of the Society in May, 1920, it was reorganized under the name of the American Oil Chemists' Society.

Its aim can be no better expressed than in the words of Article II of its constitution:

Section 1. The object and purpose of the society shall be, first, to unite for fraternal and business purposes all chemists interested in the promotion of the chemistry of fats, oils, waxes and allied industries.

Section 2. To cultivate the ties of friendship that should exist between those who have adopted a similar profession and who enjoy common interests.

Section 3. To encourage the writing of original papers on subjects pertaining to chemical work, to foster and encourage chemical research, to promote a spirit of co-operation and interchange of ideas and to strive for the adoption of uniform methods of analysis to be used by all the members of the society.

Section 4. To exert our influence and efforts toward securing the enactment of state laws safeguarding and protecting the practice and dignity of the chemical profession.

Section 5. To place the profession on the high plane its dignity deserves, and to secure for those engaged in it adequate recognition of their services, in keeping with the years of study required to master it, and the high character of those to whom only its responsibilities should be entrusted.

All persons engaged in chemical work relating to fats, oils, waxes and allied interests are eligible for active membership provided they have had at least five years' chemical training. Its meetings are held once a year, usually in May and in conjunction with the Interstate Cottonseed Crushers'

Association. It regularly publishes its transactions and maintains the chemists' section in the *Cotton Oil Press*, a journal devoted exclusively to the interests of the edible vegetable oil industry.

Its membership, however, is not limited to chemists and technologists engaged exclusively in the edible oil trade, but includes also those interested in its so-called industrial or technical aspects. Although the entire vegetable oil industry is founded upon more or less similar practice in obtaining the oil, the unified character of the industry ceases at that point and then splits up into several rather well-defined branches, namely those of edible oil, paint, soap, vulcanization, sulphonation, etc. The oil industry is too elastic to permit any oil to be pocketed; therefore, no oil chemist should confine his interest exclusively to his given line. Since most of the oils dealt with are industrially more or less interchangeable, their chemical control and technological development can be properly fostered only by sympathetic and intimate contacts between science and industry, such as are furnished by the American Oil Chemists' Society.

Chemical Imports and Exports

Imports of chemicals, drugs, dyes and medicines continued to increase during January, according to figures which just have become available at the Bureau of Foreign and Domestic Commerce. The increase applies only to chemicals on the free list. In January, 1921, the value of chemicals imported on which no duty was charged was \$8,994,118. The value of the dutiable chemicals imported was \$3,237,732.

Exports of chemicals during January of 1921 were valued at \$9,420,043. This is a decrease from \$11,367,979, which was the value of exports in January of 1920.

The imports of colors and dyes slumped decidedly in January of 1921, as compared with the corresponding month of 1920. In January, 1921, the imports amounted to 270,833 lb. In January of 1920 the aggregate of the imports was 539,144 lb. On coal-tar products as a whole, however, there was an increase in January of 1921. In that month the value of all coal-tar products was \$1,495,375. This compares with \$1,229,116, the total value of coal-tar products imported in January of 1920.

The recession in imports of gums continued during January. The total imports during January of 1921 was 7,518,576 lb. In January of 1920 the imports were 12,328,990 lb. Imports of other chemicals and drugs which do not move in such large quantities are shown by the following:

	January	
	1920	1921
Ammonia, muriate of, lb.	599,979	41,727
Arsenic, lb.	569,562	740,976
Indigo:		
Natural, lb.	13,413	6,063
Synthetic, lb.	18,001	
Glycerine, lb.	658,630	111,701
Iodine, lb.	100	37,203
Magnesite, tons	3,613	4,366

Acids were exported during January, 1921, in somewhat less volume than in the corresponding month of 1920. In January, 1921, the exports of carbolic, nitric, picric, sulphuric and other acids were valued at \$315,562. This compares with \$490,353, the value of the exports in January, 1920. The value of dyes and dyestuffs exported in January, 1921, amounted to \$1,335,531. In January, 1920, the figure was \$1,449,153. Extracts for tanning exported in January, 1921, were valued at \$116,445, which is a decided decrease from \$500,276, the value of the exports in January of 1920. The value of the exports of the various salts of soda in January, 1921, was \$755,471. The exports in January, 1920, were valued at nearly double that sum, or \$1,361,316. Exports of chemicals which moved in less volume are shown as follows:

	January	
	1920	1921
Alcohol, wood, gal.	126,673	49,685
Calcium carbide, lb.	736,959	2,131,432
Sulphur, tons	51,019	30,222

British Columbia Industrial Notes

A loan of \$25,000, under the provincial industrial act, has been granted by the government to the Douglas Fir Turpentine Co., to assist in the development of the resinous product industry. The company's plant is situated on False Bay, Vancouver, and the company is collecting resins by a special process from Douglas fir trees, which abound in this vicinity. Turpentine, flotation oils, balsam, burgundy pitch and venice turpentine are manufactured from the material collected. It is claimed that by the method of tapping adopted the trees are not injured, but, on the other hand, the growth is stimulated—a statement that has been corroborated by the provincial forestry experts.

The Forestry Branch of the Department of Lands has published the following outputs of pulp and paper in British Columbia for last year:

	1919	1920
	Tons	Tons
Sulphite pulp	80,047	92,229
Sulphate pulp	3,473	16,380
Ground wood	99,769	108,665
Newsprint	123,607	136,832
Wrapping paper	7,202	9,792

The Consolidated Mining & Smelting Co. has shipped a large consignment of refined copper on the Empress of Russia, which sailed recently for the Orient from Vancouver.

New Arsenic Plant at Toulon, Nev.

The new arsenic plant which recently was erected at Toulon, Nev., is intended to supply from domestic sources the arsenic used in insecticides by the citrus fruit industry of the Southwest. It is stated that the bulk of the arsenic used for that purpose now is being imported from Japan.

The new plant will draw its supplies of arsenic from two extensive deposits located at Battle Mountain and Beowawe, nearby points in Nevada.

A very determined effort is being made by those interested in the development of these Nevada deposits to get an import duty on arsenic. The Committee on Ways and Means has been told that the Japanese have resorted to various methods to prevent the amount of arsenic imports from becoming known. During 1920 the official figures show imports of only 8,160,000 lb. Since large quantities of arsenic are said to have come in under other designations, it is claimed that the real imports are much higher. It also is asserted that the product from the Nevada plant will not enter into competition with other domestically produced arsenic in the territories now supplied by domestic producers, particularly those in Montana and Washington.

National Research Council Establishes Research Information Service

The National Research Council has recently established a research information service which will be a clearing house for information about the mathematical, physiological and biological sciences and their applications in industry, commerce and education. A technical staff assures an intelligent interpretation of requests and skillful search for the information desired.

Ultimately it is planned to have a specialist on the staff to represent each major division of science and technology, as well as specialists on the relation of science to industrial, commercial and educational problems.

No charge is made for replies to inquiries which do not necessitate a special search. Requests for data which can be secured only by expending considerable time are acknowledged with an estimate of the necessary cost of assembling what is desired.

Further information may be secured from the Research Information Service of the National Research Council, Washington, D. C.

Aluminum Production in 1920

The value of primary aluminum produced in the United States in 1920, according to reports received by the U. S. Geological Survey, was \$41,375,000, as compared with \$38,558,000 in 1919. The market prices throughout the year have been nearly constant, ranging from 32c. to 33c. per lb.

Book Reviews

LEHRBUCH DER EISEN UND STAHLGIESSEREI (Text Book on Iron and Steel Founding). By *Prof. B. Osann*. Leipzig: Wilhelm Engelman, 1920. Price, 42 marks in paper cover, 52 marks in cloth both plus export tax, at present 175 per cent.

Every book written by Prof. Osann is characterized by thoroughness and technical value. This new (fourth) edition is an amplification of the original work, 170 added pages bringing the information contained up to date. The thoroughness displayed by the author accounts for the retention of much obsolete matter, from which, however, one who wishes can learn what not to do. The effect of American foundry literature is plainly manifest throughout the book, and indeed this is generously acknowledged by the author.

After a general classification of iron products, a few pages are given to the technology of combustion and refractory linings. The history of cast iron is given in very condensed form, which is rather astonishing in a German book. Pig iron, "direct" metal from the blast furnace for castings, come next and then a short comparison of melting methods. The crucible melting process and its derivatives follow, and then we have twenty pages on the air furnace. Much of value is given in this connection, particularly the calculation of furnace dimensions—of which little has been published heretofore. Since the steel casting is involved, the open-hearth and converter processes are explained.

Ninety pages are devoted to cupola practice to bring the subject as up to date in Germany as we know it here. The greater familiarity of the author with the blast furnace is plainly evident, as he misses some of the important requirements of cupola charging, and dismisses the oil-fired cupola with two lines.

The chemistry and physics of cast iron are gone into quite thoroughly. Unfortunately, the information is quite scattered, but none the less faithfully recorded somewhere in the book. The action of the elements in iron castings, a list of recommended compositions for castings, the varieties of pig and scrap used in mixture-making, ferro-alloy additions, and the effect of remelting are taken up in succession.

Next come the methods of testing cast iron and castings for strength, contraction, shrinkage, hardness, casting strains, chill, etc. The art of molding follows, with fifty pages of material on molding machines, after which the several methods of molding are gone into thoroughly, with many examples. Permanent molds, foundry rigging, flasks, etc., are described, and special chapters on pipe making, car wheels, and other standard branches of the art follow. Pouring methods with the recent advances in centrifugal pouring, mold drying methods, core-making, molding sand preparation—in which Europe is somewhat ahead of us—are given. The disposition of foundry refuse is also taken up specially.

The steel casting comes next, with twenty-seven pages; and "malleable" follows with twenty more. Cleaning methods from hand brushing to the sand blast are gone into. The "burning on" of defective work, traveling and other cranes follow, and the book is completed by chapters on the foundry lay-out, foundry costs, and finally a chapter on the metallography of cast iron.

Perhaps the most serious criticism of this otherwise admirable book can be directed against the sequence of the material contained. One has to consult the not too copious index to find a lot of things which seem to be thrown in at random. None the less most of the information required for an operating foundry is there. The book deserves to be added to the working library of every foundryman and engineer able to handle the German language, as it is unquestionably the standard foundry book for Continental Europe.

RICHARD MOLDENKE.

Personal

Dr. C. L. ALSBERG has resigned as chief of the Bureau of Chemistry, Department of Agriculture, to accept the directorship of the food research institute of Leland Stanford University, which is founded by the Carnegie Corporation grant. Dr. Alsberg's resignation will take effect in the early summer, as soon as his successor can be obtained.

C. K. CALVERT has resigned as chemist and bacteriologist with the Indianapolis Water Co. His place has been taken by Norman D. Doane of Meadville, Pa.

CHRISTIAN CHRISTENSEN of Washington, D. C., has opened a laboratory and office in the Transportation Building, Indianapolis, Ind., for consulting work in engineering problems of a chemical nature.

Dr. W. R. CLEMENTS, head physician at the Repauno plant of E. I. du Pont de Nemours & Co., gave an interesting address recently before the members of the Delaware Safety Council, Wilmington, on the subject of "General Industrial Health."

H. A. DEFRIES has resigned his position as vice-president of Hamilton & Hansell, Inc., New York City, and has opened offices at 15 Park Row, New York City, as a consulting engineer and metallurgist, specializing in electric-furnace construction and electrometallurgy.

A. M. FAIRLIE of Atlanta, Ga., was in New York City recently on business.

HAROLD A. HARTT, who recently was graduated from Cornell University, is now research chemist in the moving picture department of the research laboratory of the Eastman Kodak Co., Rochester, N. Y.

ELMER F. JOURDAIN, of the U. S. Industrial Alcohol Co., addressed the Chicago Chemists Club, March 1, on the restrictions covering the use of alcohol in laboratories.

Dr. A. E. KOENIG resigned as assistant professor of chemistry at the University of Wisconsin to become associate professor of chemistry at the State School of Chemistry at the State School of Mines, Butte, Mont.

S. C. LOO, technical adviser to the Leather and Wool Commission and the Board of Communication, Peking, China, is touring the United States gathering information on apparatus for chemical plants. His address in the United States is care of the Chinese Legation, Washington, D. C.

JESSE P. LYMAN, Boston, Mass., has been elected president of the American Glue Co., to succeed King Upton, who died recently at his home at Marblehead. Mr. Lyman was president of the company from 1905 to 1918, resigning to be relieved of the duties of the office. He has been treasurer since 1907.

F. B. ORTMAN, who has been for some time associated with the staff of the Northwestern Terra Cotta Co., Chicago, Ill., has resigned to become vice-president and general manager of the Tropico Potteries, Inc., Los Angeles, Cal.

ARTHUR E. RICE has been elected president of the Pennsylvania Salt Co., Philadelphia, Pa., succeeding Joseph Moore, Jr., who died recently. Mr. Rice has recently been vice-president of the company, and treasurer previous to that. Edward Armstrong, for many years superintendent of the company's plant at Pittsburgh, has been elected vice-president, succeeding Mr. Rice.

Major ALFRED L. ROCKWOOD and Captain ADRIAN ST. JOHN, of the Chemical Warfare Service, have been ordered to Fort Leavenworth for duty as student officers at the School of the Line for the year 1921-1922.

Dr. C. B. THWING, president of the Thwing Instrument Co., is taking a much-needed rest in Florida for a month as the guest of his brother, F. H. Thwing, at Orlando.

F. B. TOUGH, petroleum technologist of the Bureau of Mines, has been made supervisor of oil and gas operations, with headquarters in the Custom House Building, Denver, Col.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, March 21, 1921.

The chemical market during the past week showed a more or less potential buying power. This, together with reduced stocks, imparted greater confidence in the trade outlook. There seemed to be more confidence, however, than actual performance, but all the indications pointed to a slow and steady rehabilitation in the industry.

It is generally admitted that the foreign situation of today is exceedingly problematical and might well cause anxiety among buyers who have taken advantage of the low prices named. Yet the actual new buying for the period under review could not be termed active and the inquiries received seemed to have a feeling out character to ascertain the status of the market here. Several prominent interests close to the pulse of domestic trading stated that during the latter part of the week more inquiries were received than during the entire month of February. Developments are being keenly awaited and sellers are expecting some shift of operations from foreign to domestic chemicals. Another feature of foreign chemicals has materialized in sales of English *soda ash*. Some small-lot business has been placed in this chemical at \$1.90 per 100 lb. N. Y., and it is understood that orders can be taken at this figure for prompt shipment from England. Imported *prussiate of soda* has weakened the market considerably for that chemical. The return of large quantities of American *caustic potash* from foreign ports has kept prices uncertain, while various grades of *chlorate of potash* have been on the market at prices well below the views of domestic producers.

DEMAND FROM INDUSTRIAL PLANTS IRREGULAR

Textile mills have bought moderately, although the general disposition of all Eastern mills is to purchase conservatively. Soapmakers seem to be showing more interest and prominent dealers among rubber manufacturers stated that they have noted a perceptible improvement in the call for miscellaneous chemicals. Tanneries are not interested in any marked degree. The demand from paint and glass manufacturers is quite irregular and without any tint of real snap. The closing down of some large chemical producing plants on account of the low prevailing prices is indicative at least that the reaction of values has gone its limit and that crude materials have got to decrease if any further downward revisions are to be expected in finished products.

On account of the recent slump in alcohol prices first hands have reduced *formaldehyde* to 15½¢@16¢. per lb. *Acetic acid* is somewhat lower. *Oxalic acid* closed higher under an improved inquiry. *Sulphuric acid* consumers seemed to be more attentive of late and producers have noticed this improvement with revisions in prices. *Caustic soda*, *bichromate of soda* and *soda ash* displayed a slightly easier tendency, although buyers have experienced some difficulty in getting any round lots. A fair amount of *bleach* business was placed at 2½¢. per lb. f.o.b. works for prompt and forward shipments to papermakers. Export business continued slow, although conditions appear to be crystallizing in a more favorable light for improvement. The strong recovery in exchange rates during the past week was a satisfactory development.

GENERAL CHEMICALS

Leading producers of *copper sulphate* report a slightly easier market for standard brands, 99 per cent, large crystals. Carlots are obtainable at 5½¢. per lb., while the small crystals, 98½-99 per cent, can be purchased at 5¼¢. per lb. A fairly active inquiry has reached the market from several European centers along the Mediterranean coast and also from France. It seems that German competition is keen enough to restrict any real business, as the price named by Germany c.i.f. those ports is about the cost of

production in America. The demand from domestic consumers has remained quiet. Buyers are hesitating because they believe that the market will go lower. Textile mills are buying sparingly and the movement to dyestuffs plants is far below that of last year. Makers of insecticides are also hesitating, awaiting any new revision in prices. Isolated lots of *prussiate of soda* sold as low as 13c. per lb. during the week, but most sellers were not eager to shade 13½c. An irregular call from the consuming trade has been experienced and transactions as a rule were confined to small tonnage lots. Solid *caustic soda* was quoted at \$3.60@\$3.75 per 100 lb., the inside figure being a domestic price and the outside an export figure. It is understood that quite a number of sales were made at out-of-town points by dealers for nearby shipments at the inside quotation. Outside brands can be purchased below these prices. Resale lots of standard brands are quite difficult to be found and the market showed a firmer tendency. Producers' prices remained unchanged at 3½c. per lb., basis 60 per cent, f.o.b. works for prompt and future shipments.

There are sellers of small lots of *bichromate of potash* at 13@13½c. per lb. Reports were current that scattered lots have occasionally been sold a shade under the inside price. The demand is quiet and there is no special feature to trading. Large consumers are receiving their supplies through regular contract channels. Resale lots of *soda ash* in single bags were offered by dealers at \$1.95@\$2.05 per 100 lb. Limited quantities of barrels were quoted at 2½c. per lb. Imported ash is obtainable at \$1.90 per 100 lb. Sales were not heavy during the week, but the tendency of prices continued steady. Anxiety over receiving shipments from abroad has strengthened the inquiry for *oxalic acid* in the local market and prices at the close of the week were considerably higher, with sellers naming 17½@20c. per lb. Some prominent dealers were naming prices all the way up to 25c. per lb. for prime domestic material. Resale *formaldehyde* is on the market at 16@16½c. per lb., but producers have lowered their price to a level which now offers keen competition. The minimum price now heard in first-hand quarters for large lots is 15½c. and 16c. per lb. and upward for small quantities. Trading in *bichromate of soda* during the past week has not shown much improvement. Limited quantities of resale material have been taken by buyers at prices ranging from 7½@8½c. per lb. Sellers in most quarters have not been inclined to shade 8c., but these holders have met with strong competition and the market has shown an irregular tendency. Futures have been practically neglected and the market was in a nominal condition.

COAL-TAR PRODUCTS

Improvement, while not general, has certainly made its appearance in various quarters of the coal-tar products market, which of course is traceable to and accounted for by the more extensive operations in the allied trades. Retail prices on many commodities have reached a level that is attracting the ultimate consumer, and large quantities of the accumulated stocks are being taken off the market. This seems to be particularly the case along the line of shoes, clothing and fabrics. The textile mills have increased their operations and many plants report their output substantially enlarged. An indication of the feeling as to the ultimate trend of this market is illustrated to some extent by the fact that only recently there have been some new concerns entering the manufacturing end of intermediates and dyestuffs. These factors have a good grip on the prevailing conditions and report some regular business of an encouraging nature. Sellers, including producers and dealers, are now handling what business comes their way and are going as far as they can without having to take any loss to meet buyers' views. The crude market is holding steady and considering the curtailed production and the lack of any outlook for a decrease in costs, firmness is looked for in this end of the industry. Intermediates have deviated very little during the week. Any firm orders were met with considerable shading in all quarters.

Producers report a fairly steady demand for supplies of *para-amidophenol*. Sellers seem to be in a good position on available material and quote the market at \$1.90@\$2 per

lb. for the base and \$2.10@\$2.20 for the HCl material. Trading in the market for *diethylaniline* continued along quiet lines with the demand routine for small lots. Supplies are available in fair volume on a basis of \$1.20@\$1.30 per lb. Consumers showed an added interest in *para-phenylenediamine* during the week and prices have held steady at \$1.90@\$2 per lb. During the year 1918, 215,148 lb., valued at \$3.68 per lb., was produced, while in 1919, 234,332 lb., valued at \$2.43 per lb., was manufactured. Trading in *orthonitrophenol* was reported in some quarters as fairly steady, but the lots were of a small nature. Sales are heard on a basis of 75c. per lb., but shading is possible on a firm bid. There was nothing in the way of buying to attract attention in the *nitro-benzene* market, as only a small routine business was reported in some quarters. Prices remained unchanged at 12@14c. per lb.

While the market remained easy on *aniline oil* supplies, there seems to be little pressure to sell and prices in first-hand quarters are fairly steady at 22@27c. per lb. There is a moderate amount of business reported in some directions and shading of the above prices is thought possible in some second-hand quarters on a firm order. Reports of producers of *benzene* show a fairly active market with domestic consumers quite interested and taking regular supplies, while the foreign demand is growing. Producers are steady in their views and quote on a basis of 30@36c. per gal. for the pure material and 28@32c. per gal. for the 90 per cent grade. The demand for *toluene* has remained dull and little has occurred to stimulate trading. Producers have stocks in fair volume, but production at plants has been somewhat curtailed in view of the light demand. Prices are held steady at 30@36c. per gal.

WAXES

Trading in crude *beeswax* was along routine lines, but prices were mainly on a fairly even basis throughout the week. African crude was offered at 17@20c. per lb. Brazilian was held at 25@27c. per lb. Refined wax was moving slowly at 27@32c. per lb. Leading importers report the market for *carnauba wax* unchanged, with trading comparatively quiet. Flora was available at 68@70c. per lb. and No. 2 North Country at 30@32c. per lb. The demand for *Japan wax* was limited, but with no apparent selling pressure in evidence, due to the fact that stocks on hand are small, prices were maintained at 19@20c. per lb.

With the market for crude oil moving down and export trade showing no improvement the market for *paraffine wax* closed weak with prices irregular. Scale wax, 122-124 melting point, was offered at 2½c. per lb. Fully refined, 130-132 melting point, was quoted on the basis of 5¼@6c. per lb.

The Iron and Steel Market

PITTSBURGH, March 18, 1921.

Production of steel has been still lower in the past week, the Steel Corporation's production this week being hardly over 45 per cent of capacity, against about 60 per cent last week, while independent mill operations seem to be considerably below the 25 per cent rate the independents were being credited with a fortnight ago.

For weeks past the volume of buying, including both fresh purchases and specifications against contracts, has been far below the production. The rate of buying appears to have turned upward in the past week or ten days, though only very slightly. Production on the whole continues to decline rather sharply, but the two lines are still far apart.

The case is simply that the independents have been unable to maintain their rate of production even by price cutting, while the disturbance in market values has caused Steel Corporation customers to call for a greater reduction in shipments to them than would otherwise have been the case. The Steel Corporation's shipments promise to continue declining unless consumption increases very materially, since many of the corporation's customers have stocks, accumulated recently when the shipments were in excess of consumption.

Improvement in demand is noticed particularly in the case of standard steel pipe and black and galvanized sheets. The increase in volume is slight and is noticeable only be-

cause the volume formerly was so small. There is no reason to suppose that there is reflected anything like the beginning of a general buying movement. Rather there is a reaction from a buying rate that was too low for permanence, for consumption cannot possibly cease entirely. To a slight extent there is probably reflected the advance in the season, but the full influence of the advent of spring is not yet seen.

PRICES

Bars are still quotable at 2c. and shapes and plates at 2.10c., there being no quotable change in two or three weeks, but perhaps there is a difference in that single carloads can now be bought at the prices just named. Concessions for larger tonnages with attractive specifications are possible, as formerly. The record low on plates seems to be 1.90c., made on a particularly desirable order.

Sheets are definitely lower than a week ago, single carloads being obtainable at 3.85c. for black and 5c. for galvanized, prices that ten days ago were possible only on fair sized lots, say 500 tons.

Hoops are obtainable more freely at 2.80c., against 3.05c. in the Industrial Board schedule. Cold-rolled strips can be done at 5.65c., the usual asking price being 6c., while the nominal price is 5.25c.

Steel prices are really of no particular moment at this time. There is no price issue between buyer and seller, and no reduction possible that would bring out any considerable volume of buying. Many buyers prefer to see prices maintained, as they have stocks of steel or of their manufactured goods and are more interested in disposing of these stocks than in making fresh purchases. The situation is of course one that will liquidate itself in time, and then price will be a very interesting subject to all buyers.

The Steel Corporation continues to maintain the Industrial Board prices it adhered to in 1920 when all independents advanced to higher levels. There is no prospect of the corporation taking any action in the very near future. Indications are that the corporation will probably change its system of mill and furnace operation in the course of a month or so by eliminating the 12-hour workday, but whether the change will be made in such manner as to decrease the wage cost of producing steel is merely matter for conjecture, hence it is not necessarily to be assumed that the corporation will reduce its prices at that time. Some of the corporation's customers have expressed their full approval of the corporation's policy of maintaining prices at this time and there is no evidence that buyers in general are eager for a reduction. It is a situation that must be allowed to work itself out.

Steel-producing capacity is so large, and the prospects for reducing production costs so uncertain, that if producers became careless in the matter of quoting prices the market might descend to a level that would mean loss for an indefinite period, as it would be extremely difficult to get prices up again without a demand representing approximately the full capacity, and such demand is not to be seen even in dim prospect. There has never been a demand for steel equal to the present capacity. Production during the first nine months of 1920, when demand seemed very heavy, was only 80 per cent of capacity, there being restriction by rail transportation and other conditions.

PIG IRON AND COKE

Merchant production of pig iron is extremely light, yet not all the iron produced is being shipped. Foundries appear in many cases to have fairly large stocks. It is only occasionally that there is any inquiry in the open market. The market is largely nominal at \$27 for bessemer, \$25 for basic and \$26 for foundry, f.o.b. valley furnaces. On a round tonnage lower prices could probably be done. Price is not entirely a matter of cost, since there are stocks that producers would be glad to work off, while some furnaces would probably be willing to accept orders for pig iron still to be made at less than present cost, in hope of being able to reduce cost during operation. Several Connellsville coke producers have reduced wages, and this may account for offerings of spot furnace coke at \$4.25, against \$4.50 recently the minimum.

Calcium chloride, fused, lump.....ton	27.00 - 29.00	30.00 - 32.00
Calcium chloride, granulated.....lb.	01½ - 01½	02 - 02½
Calcium hypochlorite (bleach'g powder) lb.....lb.	02½ - 02½	03 - 03½
Calcium peroxide.....lb.	-	1.25 - 1.50
Calcium phosphate, tribasic.....lb.	-	15 - 16
Camphor.....lb.	-	72 - 75
Carbon bisulphide.....lb.	08 - 08½	09 - 09½
Carbon tetrachloride, drums.....lb.	10 - 10½	11 - 12
Carbonyl chloride (phosgene).....lb.	-	75 - 1.00
Caustic potash (see potassium hydroxide).....	-	-
Caustic soda (see sodium hydroxide).....	-	-
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	08 - 09	09½ - 10
Chloroform.....lb.	-	38 - 40
Cobalt oxide.....lb.	-	3.00 - 3.10
Copper as (see iron sulphate).....	-	-
Copper carbonate, green precipitate.....lb.	22 - 23	24 - 25
Copper cyanide.....lb.	-	60 - 62
Copper sulphate, crystals.....lb.	05½ - 05½	06 - 06½
Cream of tartar (see potassium bitartrate).....	-	-
Epsom salt (see magnesium sulphate).....	-	-
Ethyl Acetate Com. 85%.....gal.	-	1.00 - 1.00
Ethyl Acetate pure (acetic ether 98% to 100%).....	-	-
Formaldehyde, 40 per cent.....lb.	15 - 16	16 - 16½
Fusel oil, ref.....gal.	-	4.00 - 4.50
Fusel oil, crude.....gal.	-	2.50 - 2.75
Glauber's salt (see sodium sulphate).....	-	-
Glycerine, C. P. drums extra.....lb.	-	19 - 20
Iodine, resublimed.....lb.	-	3.75 - 3.85
Iron oxide, red.....lb.	-	10 - 20
Iron sulphate (copperas).....100 lb.	1.15 - 1.25	1.50 - 1.75
Lead acetate.....lb.	-	14½ - 16
Lead arsenate.....lb.	11 - 12	12½ - 13
Lead nitrate.....lb.	-	15 - 20
Litharge.....lb.	08½ - 09	09½ - 10
Lithium carbonate.....lb.	-	1.25 -
Magnesium carbonate, technical.....lb.	10½ - 11	11½ - 12
Magnesium sulphate, U. S. P.....100 lb.	2.25 - 2.75	-
Magnesium sulphate, commercial.....100 lb.	-	1.70 - 2.00
Methanol, 95%.....gal.	-	88 - 92
Methanol, Colombian spirits.....gal.	-	1.20 - 1.25
Nickel salt, double.....lb.	-	12 - 12½
Nickel salt, single.....lb.	-	13 - 13½
Phosgene (see carbonyl chloride).....	-	-
Phosphorus, red.....lb.	45 - 46	47 - 50
Phosphorus, yellow.....lb.	-	35 - 37
Potassium bichromate.....lb.	12 - 13	13½ - 14

		Carlots	Less Carlots
Potassium bitartrate (cream of tartar)	lb.	\$.35 — .40	\$0.30 — \$0.35
Potassium bromide, granular	lb.	.35 — .40	.20 — .40
Potassium carbonate, U. S. P.	lb.	.08 — .08½	.09 — .10
Potassium carbonate, crude	lb.	.08 — .10	.11 — .15
Potassium chlorate, crystals	lb.	.10 — .11	.40 — .45
Potassium cyanide	lb.	.10 — .11	.12 — .13
Potassium hydroxide (caustic potash)	lb.	.10 — .11	.12 — .13
Potassium muriate	ton	60.00 — 70.00	
Potassium iodide	lb.	.09½ — .09½	2.75 — 3.00
Potassium nitrate	lb.	.45 — .46	.10 — .12½
Potassium permanganate	lb.	.50 — .52	.48 — .50
Potassium prussiate, red	lb.	.25 — .26	.53 — .55
Potassium prussiate, yellow	lb.		.27 — .28
Potassium sulphate (powdered)	per uni.		2.25
Rochelle salts (see sodium potas. tartrate)			
Salammoniac (see ammonium chloride)			
Sal soda (see sodium carbonate)			
Salt cake	ton		30.00 — 33.00
Silver cyanide	oz.		1.30 — 1.35
Silver nitrate	oz.		.38 — .40
Soda ash, light	100 lb.	1.95 — 2.10	2.15 — 2.40
Soda ash, dense	100 lb.	2.20 — 2.30	2.40 — 2.60
Sodium acetate	lb.	.05½ — .05½	.06 — .06½
Sodium bicarbonate	100 lb.	2.60 — 2.75	3.00 — 3.25
Sodium bichromate	lb.	.08 — .08½	.08½ — .08½
Sodium bisulphate (nitre cake)	ton	7.00 — 7.50	8.00 — 11.00
Sodium bisulphate powdered, U.S.P.	lb.	.05½ — .05½	.06 — .06½
Sodium borate (borax)	lb.	.07 — .08	.08½ — .08½
Sodium carbonate (sal soda)	100 lb.	1.90 — 2.00	2.25 — 2.50
Sodium chlorate	lb.	.10 — .10½	.10½ — .11
Sodium cyanide, 96-98 per cent	lb.	.20 — .22	.23 — .30
Sodium fluoride	lb.	.13 — .13½	.14 — .14½
Sodium hydroxide (caustic soda)	100 lb.	3.60 — 3.70	3.80 — 4.00
Sodium hyposulphite	lb.		.03½ — .04
Sodium nitrate	100 lb.	2.75 —	2.85 —
Sodium nitrite	lb.	.06 — .06½	.06½ — .07
Sodium peroxide, powdered	lb.	.30 — .31	.32 — .34
Sodium phosphate, dibasic	lb.	.04½ — .04½	.05 — .05½
Sodium potassium tartrate (Rochelle salts)	lb.	.14 — .14½	.14½ — .14½
Sodium prussiate, yellow	lb.	1.25 — 1.35	1.40 — 1.50
Sodium silicate, solution (40 deg.)	lb.	.03 — .03½	.03½ — .03½
Sodium silicate, solution (60 deg.)	lb.	1.75 — 2.00	2.25 — 2.50
Sodium sulphate, crystals (Glauber's salt)	100 lbs.	.05 — .05½	.05½ — .06
Sodium sulphide, crystal, 60-62 per cent (conc.)	lb.	.04 — .04½	.04½ — .05
Sodium sulphite, crystals	lb.	.16 — .16½	.16½ — .17
Strontium nitrate, powdered	lb.	.07 — .07½	.07½ — .08
Sulphur chl ride, red	lb.	16.00 — 20.00	.08 — .09
Sulphur, crude	ton	.08 — .08½	2.25 — 3.10
Sulphur dioxide, liquid, cylinders	lb.		2.00 — 2.75
Sulphur (sublimed), flour	100 lb.		
Sulphur, roll (brimstone)	100 lb.		
Tin bichloride, 50 per cent	lb.	.18 — .19	.40 — .42
Tin oxide	lb.	.16 — .18	.19 — .20
Zinc carbonate, precipitate	lb.	.11 — .11½	.11½ — .12
Zinc chloride, gran.	lb.	.45 — .49	.50 — .60
Zinc cyanide	lb.	.12 — .13	.13½ — .14
Zinc dust	lb.	.09 — .09½	.09½ — .10
Zinc oxide, XX	lb.	.03½ — .03½	.04 — .05
Zinc sulphate	lb.		

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude	lb.	\$1.10 — \$1.15
Alpha-naphthol, refined	lb.	1.45 — 1.50
Alpha-naphthylamine	lb.	.38 — .40
Aniline oil, drums extra	lb.	.22 — .26
Aniline salts	lb.	.28 — .32
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.00 — 1.50
Benzidine, base	lb.	.95 — 1.05
Benzidine sulphate	lb.	.80 — .90
Benzoic acid, U.S.P.	lb.	.65 — .70
Benzoate of soda, U.S.P.	lb.	.65 — .70
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzyl chloride, 95-97%, refined	lb.	.30 — .35
Benzyl chloride, tech.	lb.	.25 — .30
Beta-naphthol benzoate	lb.	3.50 — 4.00
Beta-naphthol, sublimed	lb.	.70 — .75
Beta-naphthol, tech.	lb.	.35 — .45
Beta-naphthylamine, sublimed	lb.	2.25 — 2.40
Cresol, U. S. P., in drums (100 lb.)	lb.	.16 — .18
Ortho-cresol, in drums (100 lb.)	lb.	.23 — .25
Cresylic acid, 97-99%, straw color, in drums	gal.	.90 — .95
Cresylic acid, 75-97%, dark, in drums	gal.	.85 — .90
Cresylic acid, 50%, first quality, drums	gal.	.55 — .60
Dichlorobenzene	lb.	.06 — .09
Diethylaniline	lb.	1.20 — 1.30
Dimethylaniline	lb.	.55 — .65
Dinitrobenzene	lb.	.30 — .32
Dinitrochlorobenzene	lb.	.25 — .30
Dinitronaphthalene	lb.	.33 — .35
Dinitrophenol	lb.	.40 — .45
Dinitrotoluene	lb.	.27 — .30
Dip oil, 25%, tar acids, car lots, in drums	gal.	.38 — .40
Diphenylamine	lb.	.60 — .70
H-acid	lb.	1.30 — 1.50
Meta-phenylenediamine	lb.	1.25 — 1.30
Monochlorobenzene	lb.	.14 — .16
Monoethylaniline	lb.	1.75 — 2.00
Naphthalene crushed, in bbls. (250 lb.)	lb.	.08 — .08½
Naphthalene, flake	lb.	.08 — .08½
Naphthalene, balls	lb.	.09½ — .10½
Naphthionic acid, crude	lb.	.70 — .75
Nitrobenzene	lb.	.12 — .15
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	.18 — .25
Ortho-amidophenol	lb.	3.20 — 3.75
Ortho-dichlor-benzene	lb.	.15 — .20
Ortho-nitro-phenol	lb.	.75 — .80
Ortho-nitro-toluene	lb.	.20 — .24
Ortho-toluidine	lb.	.25 — .30
Para-amidophenol, base	lb.	1.90 — 2.00
Para-amidophenol, HCl	lb.	2.10 — 2.20

Para-dichlorobenzene	lb.	.15 — .20
Paranitroaniline	lb.	.85 — .90
Para-nitrotoluene	lb.	.90 — 1.05
Para-phenylenediamine	lb.	1.90 — 2.00
Para-toluidine	lb.	1.30 — 1.60
Phthalic anhydride	lb.	.55 — .60
Phenol, U. S. P., drums (dest.), (240 lb.)	lb.	.12 — .14
Pyridine	gal.	2.00 — 3.50
Resorcinol, technical	lb.	1.85 — 2.00
Resorcinol, pure	lb.	2.30 — 2.50
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.22 — .23
Salicylic acid, U. S. P.	lb.	.25 — .27
Salol	lb.	.85 — .95
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.28 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.16 — .18
Sulphanilic acid, crude	lb.	.30 — .35
Tolidine	lb.	1.35 — 1.45
Toluidine, mixed	lb.	.40 — .45
Toluene, in tank cars	gal.	.28 — .32
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.42 — .45
Xylene, pure, in tank cars	gal.	.45 — .45
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark	lb.	\$0.24 — \$0.26
Beeswax, refined, light	lb.	.27 — .28
Beeswax, white pure	lb.	.40 — .45
Carnauba, Fl ra.	lb.	.68 — .70
Carnauba, No. 2, North Country	lb.	.30 — .32
Carnauba, No. 3, North Country	lb.	.18 — .19
Japan	lb.	.19½ — .20
Montan, crude	lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.03½ — .03½
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.03 — .03½
Paraffine waxes, refined, 118-120 m.p.	lb.	.04 — .04½
Paraffine waxes, refined, 125 m.p.	lb.	.05 — .05½
Paraffine waxes, refined, 128-130 m.p.	lb.	.05 — .06
Paraffine waxes, refined, 133-135 m.p.	lb.	.06½ — .06½
Paraffine waxes, refined, 135-137 m.p.	lb.	.07 — .07½
Stearic acid, single pressed	lb.	.11 — .11
Stearic acid, double pressed	lb.	.11½ — .11½
Stearic acid, triple pressed	lb.	.12 — .12½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940	gal.	\$1.70
Pine oil, pure, dest. dist.	gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970	gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990	gal.	.37
Pinewood creosote, ref.	gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl.	280 lb.	\$6.25 —
Rosin E-1	280 lb.	6.25 —
Rosin K-N	280 lb.	6.25 —
Rosin W. G.-W. W.	280 lb.	6.50 —
Wood rosin, bbl.	280 lb.	6.75 —
Spirits of turpentine	gal.	.59 —
Wood turpentine steam dist	gal.	.53 —
Wood turpentine, dest. dist.	gal.	.52 —
Pine tar pitch, bbl.	200 lb.	— 7.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	— 14.50
Retort tar, bbl.	500 lb.	15.00 — 14.75
Rosin oil, first run	gal.	.45 —
Rosin oil, second run	gal.	.48 —
Rosin oil, third run	gal.	.60 —

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)	gal.	.39
68-70 deg., steel bbls. (85 lb.)	gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.30

Crude Rubber

Para-Upriver fine	lb.	\$0.17 — \$0.18
Upriver coarse	lb.	.13 — .14
Upriver caucho ball	lb.	.14 — .14½
Plantation—First latex crepe	lb.	.19½ —
Ribbed smoked sheets	lb.	.17½ —
Brown crepe, thin, clean	lb.	.18 —
Amber crepe No. 1	lb.	.20 —

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls.	lb.	\$0.08½ — \$0.09
Castor oil, AA, in bbls.	lb.	.10 — .10½
China wood oil, in bbls. (f.o.b. Pac. coast)	lb.	.07½ — .08
Cocoonut oil, Ceylon grade, in bbls.	lb.	.09½ — .09½
Cocoonut oil, Cochinchina grade, in bbls.	lb.	.09½ — .10
Corn oil, crude, in bbls.	lb.	.08 — .08½
Cottonseed oil, crude (f. o. b. mill)	lb.	.04 —
Cottonseed oil, summer yellow	lb.	.06½ — .06½
Cottonseed oil, winter yellow	lb.	.07 — .07½
Linseed oil, raw, car lots (domestic)	gal.	.65 — .68
Linseed oil, raw, tank cars (domestic)	gal.	.58 —
Linseed oil, in 5-bbl lots (domestic)	gal.	.67 —

Olive oil, commercial.....	gal.	\$2.00	—	\$2.50
Palm, Lagos.....	lb.	.07½	—	.07½
Palm, Niger.....	lb.	.06½	—	.06½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.05½	—	.06
Peanut oil, refined, in bbls.....	lb.	.11	—	.11½
Rapeseed oil, refined in bbls.....	gal.	1.05	—	1.10
Rapeseed oil, blown, in bbls.....	gal.	1.15	—	1.20
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07	—	.07½
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04	—	

FISH

Light pressed menhaden.....	gal.	\$0.45	—	\$0.47
Yellow bleached menhaden.....	gal.	.47	—	
White bleached menhaden.....	gal.	.49	—	
Blown menhaden.....	gal.	.84	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	17.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.00	—	
Blanc fixe, dry.....	lb.	.05	—	.05½
Blanc fixe, pulp.....	net ton	50.00	—	60.00
Casein.....	lb.	.14	—	.16
Chalk, domestic, extra light.....	lb.	.05	—	.05½
Chalk, domestic, light.....	lb.	.04½	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04½	—	.05
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (kaolin), imported, lump.....	net ton	23.00	—	25.00
China clay (kaolin), imported, powdered.....	net ton	30.00	—	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Fla.....	net ton	25.00	—	
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	30.00	—	35.00
Graphite, Ceylon lump, first quality.....	lb.	.08	—	.09
Graphite, Ceylon chip.....	lb.	.07	—	.08
Graphite, higher lubricating grades.....	lb.	.11	—	.40
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic lump.....	lb.	.05	—	.05½
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.57	—	
Shellac, orange superfine.....	lb.	.62	—	
Shellac, A. C. garnet.....	lb.	.45	—	
Shellac, T. N.....	lb.	.47	—	
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	14.00	—	15.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	12.00	—	22.00
Talc, roofing grades, f.o.b. Vermont.....	ton	9.50	—	15.00
Talc, rubber grades, f.o.b. Vermont.....	ton	12.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	12.00	—	15.00
Talc, imported.....	ton	40.00	—	50.00
Talc, California talcum powder grade.....	ton	20.00	—	40.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	160		
Chrome brick, f.o.b. Eastern shipping points.....	net ton	80-100		
Chrome cement, 40-45% Cr ₂ O ₃	net ton	45-50		
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton		55	
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	55-60		
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	45-50		
Magnesite brick, 9-in. straight.....	net ton	100		
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	105		
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	120		
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	65-70		
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	56-61		
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	50-60		

Ferro-Alloys

All f.o.b. Works

Ferro-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, carlots.....	lb.	.15	—

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

SELMA—G. W. Tidd and associates have plans under way for the erection of a new plant at Tuscaloosa, Ala., for the manufacture of cement brick and kindred products. The factory will be equipped for a daily production of about 25,000 bricks.

California

LOS ANGELES—The Co-operative Glass Co., Bank of Italy Bldg., has awarded a contract to the Pozzo Construction Co., 421 Macy St., for the erection of a new 1-story and basement plant at Daly and Richmond Sts., consisting of two buildings, 91 x 180 ft. and 40 x 75 ft., respectively. The plant will cost about \$48,000.

MERCED—The California Pottery Co. will construct a total of 32 kilns at its new local plant, now in course of construction, and it is planned to commence operations in certain departments of the plant during April. It will give employment to about 300 operatives.

Georgia

SAVANNAH—A portion of the plant of the Atlantic Turpentine & Pine Tar Co., Central Junction, near Savannah, was destroyed by fire, March 4, with loss estimated at \$75,000.

Illinois

CHICAGO—The American Vat Color Co., of Chicago, Ill., has leased a building at 3223 South Western Ave., for manufacturing purposes.

Indiana

HAMMOND—The Standard Oil Co. of Indiana has purchased a 160-acre tract of land located in the cities of Hammond and Whiting, Ind., to make space for contemplated additions to existing plant.

Iowa

NEVADA—The Mason City Brick & Tile Co., Mason City, Ia., is considering the erection of a new brick and tile manufacturing plant at Nevada, to cost about \$250,000 with machinery. B. C. Keller is head.

Louisiana

SHREVEPORT—The Great Southern Producing & Refining Co., Indianapolis, Ind., has plans under way for the erection of a new unit at its Shreveport oil refinery. J. F. A. Moore, 900 Euclid Ave., Cleveland, O., is engineer.

BRAITHEWAITE—The Braithewaite Paper Co. is planning for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at \$75,000.

BASTROP—The Bastrop Pulp & Paper Co. has plans under way for the construction of a new pulp and paper mill. The first unit of the plant, estimated to cost about \$75,000, will be devoted to pulp production, and at a later date will be followed by the proposed paper mill.

Maryland

BALTIMORE—Victor C. Blode, Caton and Carroll Sts., manufacturer of chemicals, is planning for the rebuilding of the section of his plant damaged by fire on March 3.

BALTIMORE—Fire, March 3, caused a considerable loss at the plant of the Martin Fertilizer Co., Clinton and Fourth Sts., with damage including the acid and condenser departments.

Massachusetts

SALEM—The John C. Dow Leather Co., recently incorporated with a capital of \$50,000, has acquired the local plant of the Berkovitch-Mishel Leather Co., and will specialize in the manufacture of sheep leathers from pickled sheepskins. The plant will be equipped for color production, including black. John C. Dow, 106 South St., Boston, heads the company.

STURBRIDGE—George Kanutzen and George Kanutzen, Jr., are planning for the operation of local graphite properties. It is proposed to develop an extensive capacity at a site previously operated, but closed down some months ago.

Michigan

KALAMAZOO—The Kalamazoo Vegetable Parchment Co. is planning to break ground early in May for the erection of its proposed new local paper mill, comprising a two-machine addition to its present plant, 80 x 900 ft., and estimated to cost about \$400,000 with machinery. Billingham & Cobb, Press Bldg., are architects and engineers. J. Kindler is president.

WELLS—The Delta Chemical Co. is reported to be planning for the rebuilding of its plant, destroyed by fire, March 8, with loss estimated at \$500,000, including machinery. R. B. Goetschaus is president.

Minnesota

ST. PAUL—The James Roe Glass Co., 109-13 East Ninth St., is planning for the rebuilding of the portion of its plant destroyed by fire, Feb. 27, with loss of about \$25,000.

New Jersey

TRENTON—Walter L. Collins, 64 Grove St., Milford, Mass., has made application to the local Chamber of Commerce for a plant or plant site, for the establishment of a new tile-manufacturing plant. The works will be used for the production of ceramic tiling under a new process. A company is now being organized by Mr. Collins. Secretary Conover, Trenton Chamber of Commerce, is in charge of the proposition.

BAYONNE—The Union Sulphur Co., 17 Battery Pl., New York, has acquired a tract of property in the Bergen Point district with frontage on the Kill van Kull of about 400 ft., and extending on First St. to the foot of Avenues C and D. The site will be used for a new works at a later date. At the present time the company will construct a large service building.

CARNEY'S POINT—E. I. du Pont de Nemours & Co., Wilmington, Del., is planning for the construction of a new color-manufacturing plant in this section. It is said that the proposed factory will be one of the largest dry color plants in the world, ultimately giving employment to over 20,000 operatives. The company is also reported to be arranging for the erection of a new lithopone plant.

New York

MASPEETH, L. I.—The Gleason Tiebout Glass Co., has filed plans for extensions and improvements in its plant on Flushing Ave., near Garrison St.

BROOKLYN—Fire, March 10, destroyed a portion of the Sone & Fleming Oil Works of the Standard Oil Co., Greenpoint and Kingsland Aves., with loss estimated at \$150,000. It will be rebuilt.

North Carolina

HENDERSON—The Vance Guano Works, a subsidiary of the American Agricultural Chemical Co., 2 Rector St., New York, is planning for the rebuilding of its local plant, with number of new extensions. The work, including equipment, is estimated to cost about \$500,000. A capacity of about 50,000 tons of fertilizer per annum will be developed.

GREENSBORO—The Guilford Mining Co., 335 Harrison Apartments, recently organized, is planning for the development of copper and other mineral properties in the vicinity of Guilford, N. C. Considerable machinery for operation will be installed at an early date. J. C. White and R. F. Titsworth, Knoxville, Tenn., head the company.

ROSE HILL—The Rose Hill Brick & Tile Co. has plans under way for the erection of a new local plant for the manufacture of cement tiling and kindred products. G. B. D. Parker, Chinquapin, N. C., is president.

Ohio

NEWARK—The American Bottle Co. has plans under way for the erection of a new building at its plant, 1-story, 250 x 500 ft.

The DeVore Co., 908 Nicholas Bldg., Toledo, O., is architect.

PIQUA—The American Strawboard Co., manufacturer of corrugated fiber products, has preliminary plans under way for the erection of a new 1 story plant. Headquarters of the company are at Akron, O.

BARNESVILLE—The Kearns-Gorsuch Glass Co., a subsidiary of the Hazel-Atlas Glass Co., Wheeling, W. V., is reported to be planning for the rebuilding of its local plant, destroyed by fire, March 3, with loss estimated in excess of \$500,000, including machinery. The company manufactures fruit jars, etc.

CAMBRIDGE—The Flannagan Pottery Co. is taking bids for the erection of an addition to its kiln department to cost about \$20,000.

WOOSTER—The Stellar Refinery Co. has completed plans for the erection of a new oil-refining plant in the vicinity of Cincinnati. The works will include a power house and pumping plant, and are estimated to cost about \$300,000 with machinery. E. M. Quincy is vice-president.

Oklahoma

TULSA—The Wilcox Oil & Gas Co. has preliminary plans under way for the erection of a new oil refining plant, with daily capacity of close to 5,000 bbl. The company has acquired a site, totaling about 150 acres, for the refinery and will expend about \$1,500,000 on the project. A new pipe line will be built from Bristow, Okla., to a point near St. Louis, Mo. Homer F. Wilcox is president.

PONCA CITY—James Gramme and associates are planning for the construction of a new lime-manufacturing works. The company has extensive limestone deposits in this district, and will devote initial operations to raw material production. A crushing plant will be installed at an early date.

Pennsylvania

MARCUS HOOK—The Union Petroleum Co. has construction under way on a new lubricating-oil works addition, about 200 x 200 ft. It is planned to place a portion of the plant in service at an early date. The tankage department will consist of 42 tanks, each 25 ft. in diameter and 30 ft. high, with 9 agitators and accessory equipment.

NORRISTOWN—A portion of the plant of the Norris Magnesite & Asbestos Co. was damaged by an explosion on March 9. An official estimate of the loss has not been made. It is said that the plant will be rebuilt at an early date.

HARRISBURG—The Harrisburg Bag & Box Co., 1550 Vernon St., manufacturer of paper specialties, will soon commence the erection of two new plant units, 1- and 2-story, about 64 x 125 ft., estimated to cost approximately \$200,000 with machinery. R. R. Markley, Spooner Bldg., Harrisburg, is architect. Samuel E. Eby is head.

Tennessee

MEMPHIS—The Memphis Packing Co. is considering the erection of a new local soap-manufacturing plant. Details are being arranged. Joseph Newburger is president.

Texas

DENTON—The Crescent Refining Co. has completed plans for the erection of a new oil refinery on a local site, with initial capacity of about 75 bbl. per day. J. A. Minnis is president.

Washington

SEATTLE—The Fisher Flouring Mills Co., Harbor Island, is negotiating with the Public Dock Commissioners, Portland, Ore., for the use of property at the Upper Albina ferry land in connection with its proposed new mills in this section, estimated to cost about \$800,000 with machinery.

West Virginia

MORGANTOWN—H. J. Booth, Pittsburgh, has preliminary plans under way for the erection of a new glass manufacturing plant in the vicinity of Round Bottom, W. Va. A site for the factory has been secured.

HUNTINGTON—The Huntington Tumbler Co., manufacturer of glass tumblers, etc., is planning for the erection of a new plant for increased output, to consist of a 1-story factory 80 x 275 ft., with two extensions, 60 x 60 ft. and 30 x 55 ft. respectively. The new works are estimated to cost about \$135,000 with machinery. A. F. Dickey, First National Bank Bldg., Huntington, is architect.

Wisconsin

JANESVILLE—George T. Simmons, R.F.D. 8, has broken ground for the erec-

tion of a new 2-story plant at Edgerton, Wis., 60 x 155 ft., to be equipped for the manufacture and assembling of porcelain spark plugs. The factory is estimated to cost about \$100,000.

Alberta

EDMONTON—The Imperial Oil Co. and the Edmonton Gas & Power Co. are seeking power from the Alberta Government, now in session, to enable them to construct pipelines for the purpose of conveying oil and gas, respectively, through the province. The line of route is not specified.

Quebec

MONTREAL—The Brompton Pulp & Paper Co. is arranging for a bond issue of \$3,000,000, a portion of the proceeds to be used for extensions, betterments and operations.

Industrial Notes

E. I. DU PONT DE NEMOURS & Co., Wilmington, Del., makes the following announcement of changes in organization, effective Feb. 1, 1921: The miscellaneous manufacturing department will be discontinued; substituted therefor within the production department, two new departments are created to be known respectively as the dyestuffs department and the paint and chemicals manufacturing department. The dyestuffs department will be in charge of C. A. Meade, V. P., with W. F. Harrington as director. The dyestuffs sales division and the dye manufacturing division have been transferred without change of personnel to form the selling and manufacturing divisions of the new dyestuffs department. The paint and chemicals manufacturing department will also be in charge of C. A. Meade, V. P., with Hunter Grubb as director and E. C. Thompson as assistant director. R. W. Sample has been appointed manager of paint and varnish sales, Eastern division, with headquarters at 35th and Gray's Ferry Rd., Philadelphia, Pa. The sales of paints and varnishes will be consolidated under Mr. Sample at Philadelphia for all of the company's selling branches, with the exception of Boston, Chicago, New York and San Francisco. The railway, industrial and architectural representatives of the paint and varnish section will also report to Mr. Sample.

THE AMALGAMATED METALS Co., producer of brass and bronze castings, has become affiliated with the Casey-Hudson Co., manufacturer of screw machines and other machine products at Chicago. The new offices will be located in the Casey-Hudson Co., 361 East Ohio St., Chicago, Ill.

FREDERICK JOHNSTON severed his connection with Marden, Orth & Hastings in order to direct the chemical sales division of the Michigan Iron & Chemical Co., Consumers Bldg., Chicago, Ill.

THE AUSTIN MACHINERY Co., of Louisiana, has been organized under the laws of the State of Louisiana for distribution of the products of the Austin Machinery Corp. in Louisiana, Arkansas, Mississippi and Tennessee. The general offices of the company are located at 1020 Maison Blanche Bldg., New Orleans, La.

F. J. RYAN & Co., Philadelphia, Pa., specialists in electric heating problems in both the chemical and the metallurgical industry, announce the election of the following departmental executives: S. H. Ourbacker, director of engineering, F. A. Hall, director of sales, and T. B. Bechtel, director of construction. F. J. Ryan & Co. was organized by Mr. Ryan, who has been allied with the electric-furnace development since its commencement in this country. The original company was organized in 1913, but was inactive for a period of three years when he occupied the position of director and general manager of the Electric Furnace Construction Co., and later as directing manager of the American Metallurgical Corp., the active business of which was terminated last October when F. J. Ryan & Co. was incorporated. The remaining contracts of the American Metallurgical Corp. have been completed by the new organization and practically all of the executives of the old organization have become members of the new. From this time on the new organization will specialize exclusively in electrometallurgy and electrochemistry. Departments for the manufacture of low-temperature ovens have been added, and structural and machine divisions created through associations with Philadelphia shops. A New York office has been opened recently at 21 East 40th St. under the direction of E. C. Melby. Mr. Melby will have supervision over the New York district and export field. His previous experience for a number of years in the export trade, specializing with the Scandinavian countries, makes him especially adapted to this district.

THE SURFACE COMBUSTION Co., Inc., 366 Gerard Ave., Bronx, New York City, manufacturer of industrial furnaces, has acquired the entire rights and interests of the Ratiometer Corp., Rochester, N. Y. The latter company has during the last few years manufactured ratiometers in Rochester, N. Y. The Surface Combustion Co., Inc., has established a separate manufacturing and sales organization in its own plant in New York City, where it will continue this business under the name of the Ratiometer Corp. The ratiometer is a mechanical device, invented by Ivar Lundgaard, for the automatic proportioning of gaseous fuels and the air used for their combustion. The manufacturers claim this device can be readily installed on any two-pipe system, automatic temperature control being maintained entirely through the gas line. Other patent rights recently acquired by the Surface Combustion Co., Inc., are the Clark principle of intermittent firing for enameling furnaces and the Langenberg-Fetterly furnace for heat-treating armor-piercing shells.

W. E. PRINDLE, who was formerly president of the Buckeye Dryer Co., has started the manufacture of direct, indirect and steam-heated driers, as W. E. Prindle Co., Columbus, O.

THE AMERICAN GAS FURNACE Co. announces that its entire personnel will henceforth be concentrated in a main office in Elizabeth, N. J., in which city its two plants are located; also that it has discontinued selling operations through its former sole agent, E. P. Reichhelm & Co., Inc. The results of this action will be the more thorough co-operation of the various departments and will place more intimately at the disposal of its patrons the entire organization of The American Gas Furnace Co.

THE CUTLER-HAMMER MFG. Co., Milwaukee, Wis., announces the following changes in the personnel and district office territory of Milwaukee and New York: G. S. Crane, who has been manager of the Cleveland office, will become manager of controller sales at the main office in Milwaukee. L. B. Timmerman will be in charge of the Cleveland office, and will act in the capacity of assistant to A. G. Pierce, manager of the central district. The Cincinnati office will become a part of the central district, with R. I. Maujer as branch manager. E. N. Lightfoot will assume the title of manager of the heating department, with headquarters at the New York works, and will be in full charge of all matters relating to the sale of electric-heating devices.

New Companies

THE AMERICAN WOOD CHEMICAL Co., Chattanooga, Tenn., has been incorporated with a capital of \$800,000 to manufacture chemicals and byproducts. The incorporators are R. L. Frost and John S. Wrinkle, Chattanooga.

THE INDUSTRIAL POTASH CORP., capitalized at \$30,000,000, has been incorporated at Salt Lake City, Utah, to exploit the alunite deposits at Marysville, Utah. The incorporators are Ross F. Beckstrom and Jacob H. Krause of Rockford, Ill., and Francis F. Hansen and Louis Grollman of Chicago.

THE BRAZILIAN RUBBER REFINING & MFG. Co., New York, N. Y., has been incorporated with a capital of \$400,000 to manufacture refined rubber and finished rubber products. The incorporators are J. T. Coggins, F. Chamie and J. E. Strowbridge, 812 Bergen St., Brooklyn.

THE WEST LEATHER BELTING Co., Room 1021, 39 South La Salle St., Chicago, Ill., has been incorporated with a capital of \$35,000 to manufacture leather belting and kindred products. The incorporators are K. H. West, Frederic O. Mason and Edward R. Adams.

THE AMERICAN PINE PRODUCTS REFINING Co., Savannah, Ga., has been incorporated with a capital of \$250,000 to manufacture refined oils. The incorporators are H. F. Hogeborn, Savannah; B. A. Deal, Jr., Nashville, Ga.; and H. B. Elliott, Salisbury, Md.

THE TROEGER PRODUCTS CORP., Brooklyn, N. Y., has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are F. S., E. A. and J. F. R. Troeger, 648 East Thirty-fourth St., Brooklyn.

THE KORTE PRODUCTS Co., 2858 Fifth Ave., Chicago, Ill., has been incorporated with a capital of \$25,000 to manufacture chemicals and affiliated products. The incorporators are Samuel L. Goldberg, Charles Weiss and Frank Korte.

THE EAST LONG BEACH OIL Co., Inc., Long Beach, Cal., has been incorporated with a capital of \$1,000,000 to manufacture

petroleum products. The incorporators are W. LeRoy Thomas, C. A. Willis and J. F. Collins, all of Long Beach. Swaffield & Swaffield, 529 First National Bank Bldg., Long Beach, represent the company.

THE UNITED STATES PULP PRODUCTS CORP., Newark, N. Y., has been incorporated under Delaware laws with a capital of \$1,750,000 to manufacture pulp specialties. The incorporators are Lindsey Hooper, Ernest L. Fox and L. G. Rowe, Newark.

THE MCCANN-SHIELDS PAINT Co., Pittsburgh, Pa., has been incorporated with a capital of \$15,000 to manufacture paints, varnish, etc. J. E. Shields, 1820 Metropolitan St., is treasurer.

THE CRYSTAL OIL Co., Richmond, Va., has been incorporated with a capital of \$2,750,000 to manufacture refined oil products. Whiting C. Faulkner, Richmond, is president, and W. E. Bryan, Denver, Colo., secretary.

THE GUASTI FINCH CHEMICAL Co., Vernon, Cal., has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are Secondo Guasti, L. S. Finch and J. I. Barlotti, all of Los Angeles, Cal.

THE PRINCE RE-ENFORCED RUBBER Co., Boston, Mass., has been incorporated with a capital of \$50,000 to manufacture mechanical rubber products. The incorporators are Howard P. Knox, J. D. Prince and Herbert B. Morse, 140 Oliver St.

WOHL, LETRAK & Co., New York, N. Y., has been incorporated with a capital of \$10,000 to manufacture glass products. The incorporators are R. Dolgin, G. G. Rosenberg and B. Rabinowitz, 261 Broadway.

THE ERWIN CHEMICAL PRODUCT Co., New York, N. Y., has been incorporated with a capital of \$30,000 to manufacture chemicals and affiliated specialties. The incorporators are W. W. Jordan, M. P. Matthias and L. B. Erwin, Forest Hills, N. Y.

THE SANITARY CHEMICAL SPECIALTIES Co., 208 North Wells St., Chicago, Ill., has been incorporated with a capital of \$15,000 to manufacture chemical products. The incorporators are John W. and Arthur C. Tretow, and Walter H. Shryock.

THE SYKESVILLE GLASS Co., Pittsburgh, Pa., has been incorporated with a capital of \$25,000 to manufacture glass products. Dusan Botic, 2612 Sarah St., is treasurer.

THE MIDLAND CHEMICAL Co., Indianapolis, Ind., has been incorporated with a capital of \$10,000 to manufacture chemicals and affiliated products. The incorporators are H. R. Doty, L. D. Millikan and B. E. Jones.

THE OCEAN VIEW OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000 to manufacture refined oil products. The incorporators are W. G. Cline, F. H. Ballinger, Thomas F. Fitzgerald and J. H. Old, Los Angeles. George W. Bush, 431 Van Nuys Bldg., is representative.

THE HEPALIN CHEMICAL Co., Boston, Mass., has filed notice of organization to manufacture chemical products. Harry Belin and David Berman, 32 McClean St., head the company.

THE EMPIRE PAPER PRODUCTS CORP., New York, N. Y., has been incorporated with a capital of \$300,000 to manufacture paper goods. The incorporators are A. B. King, D. V. Sullivan and J. G. Miller, 261 Broadway.

THE MOULTON PRODUCING & REFINING CORP., Buffalo, N. Y., has been incorporated with a capital of \$300,000 to manufacture refined oil products. The incorporators are George Wroblewski and E. York Ames, Buffalo.

THE HERBETTA MFG. Co., Indianapolis, Ind., has been incorporated with a capital of \$85,000 to manufacture chemicals and affiliated products. The incorporators are R. L. Walker, E. E. Gates and J. C. Ralston, Indianapolis.

THE TWINING-LARGE LIME & CHEMICAL Co., Carpenterville, N. J., has been incorporated with a capital of \$50,000 to manufacture chemicals, hydrated lime and kindred products. The incorporators are Robert G. Griswold, Willis W. and Charles J. Smith, Carpenterville.

THE NATIONAL CORK PRODUCTS Co., Newark, N. J., has been incorporated with a capital of \$100,000 to manufacture cork specialties and affiliated products. The incorporators are Leonard S. Lerman, Morris Uram and James Deckert, N. M. Fruchtman, 156 Market St., is representative.

THE UNION RUBBER Co., Boston, Mass., has been incorporated with a capital of \$100,000 to manufacture rubber goods. The incorporators are Raymond D. Smith, Waltham, Mass.; Joseph W. Worthen, Winchester, Mass.; and M. E. Buchanan, Newton, Mass.

THE TUCK & RICHTER MFG. CO., Gloucester, Mass., has been incorporated with a capital of \$80,000 to manufacture ink products. The incorporators are Albert B. Tuck, Alfred O. Richter and L. D. Tuck, all of Gloucester.

THE WINCHESTER PAPER CO., White Plains, N. Y., has been incorporated with a capital of \$50,000 to manufacture paper goods. The incorporators are W. M. Gilbert, A. S. Diven and J. C. Brophy, White Plains.

THE HOME CHEMICAL MFG. & IMPORTING CO., New York, N. Y., has been incorporated with a capital of \$150,000 to manufacture chemicals and chemical byproducts. The incorporators are P. Richter, G. J. Bidel and B. Schmidt, 937 East Fifteenth St., Brooklyn.

THE POWER & CHEMICAL EQUIPMENT CO., Hoboken, N. J., has been incorporated with a capital of \$10,000 to manufacture chemical apparatus, brass goods, etc. The incorporators are Edward D. Grosso, F. T. Morgan and John J. Marnell, 77 River St.

THE NATIONAL RUBBER GOODS MFG. CORP., Akron, O., has been incorporated under Delaware laws with a capital of \$2,000,000 to manufacture rubber products. The incorporators are R. A. Stillwell, Akron; W. H. Hill and B. Williamson, Cleveland.

THE BEAUMONT MIDWAY OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000 to manufacture refined petroleum products. The incorporators are J. Drew Funk, L. K. Strobel and C. A. Weaver, Los Angeles. Alfred Barstow, 600 Kerckhoff Bldg., is representative.

THE ESSEX CHEMICAL CO., 71 Paris St., Newark, N. J., has filed notice of organization to manufacture chemicals, lacquers, etc. George N. Beck, 97 Van Cleff St., Jersey City, N. J., is representative.

THE L. R. REICH DRUG & CHEMICAL CO., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture chemicals and affiliated products. The incorporators are L. M. Warshaw, S. and L. R. Reich, 66 Reade St.

THE CALCIUM CARBONATE CO., LTD., has been formed with a capital of \$50,000 for the purpose of manufacturing whiting from a deposit of decomposed shell-lime in Kane Valley, near Merritt, B. C. The initial unit will have a capacity of 10 tons daily. Up to now practically all the whiting used in Canada has been imported from Great Britain.

New Publications

BOOKS

LESSONS IN MECHANICS. By William S. Franklin and Barry MacNutt. Pp. 221; 178 figs. Bethlehem, Pa.: Franklin and Charles, 1919 (reprinted 1920). Price, \$2.

LESSONS IN ELECTRICITY AND MAGNETISM. By William S. Franklin and Barry MacNutt. Pp. 254; 188 figs. Bethlehem, Pa.: Franklin and Charles, 1919 (reprinted 1920). Price \$2.25.

LESSONS IN HEAT. By William S. Franklin and Barry MacNutt. Pp. 147; 41 figs. Bethlehem, Pa.: Franklin and Charles, 1920. Price \$2.

While these three companion volumes in a new series of physics texts were designed primarily to meet the needs of students taking a two-year schedule in college physics, chemists who wish to review physics will find them very helpful.

Realizing that students in the courses referred to will not have had higher mathematics the methods of calculus are introduced in the first volume of the series, so that strictly mathematical proofs do not have to be sidestepped. It is felt that this training in applied mathematics will help the student not only in the study of physics but in his work in pure mathematics.

The arrangement of the text is in strict lesson order. Descriptive and explanatory matter has been reduced to a minimum and the development of every topic leads as directly as possible to illustrative numerical problems. Lists of books for reference and for additional study are given in each volume, so that any phase of the subject can be taken up in more detail. Information about the national organizations and societies relating to physical science and engineering is also included, so that the student may become interested in the activities of these bodies early in his career.

Chemists will find "Lessons on Heat" especially interesting as an introduction to the study of thermodynamics. It includes chapters on: Temperature and thermometry, expansion; heat as a form of energy, calorimetry; thermal properties of solids, liquids and gases; transfer of heat; the properties of gases, the second law of thermodynamics.

INTRODUCTION TO GENERAL CHEMISTRY. By H. Copaux, professor of mineral chemistry at the School of Industrial Physics and Chemistry of the City of Paris. Translated by Dr. Henry Leffmann. Pp. 195; 30 illustrations. Philadelphia: P. Blakiston's Son & Co., 1920.

Prof. Copaux has written in compact yet clear form an introduction to the principles of physical chemistry. The treatment throughout is thoroughly modern. Dr. Leffmann has contributed a short appendix on hydrogen-ion concentration.

CHEMICAL ANALYSIS OF STEEL-WORKS MATERIALS. By Fred Iffotson, F.I.C., of the department of metallurgy, Sheffield University. Pp. 296; 21 illustrations. London and New York: Longmans, Green & Co., 1920. Price \$7.50.

This is a revision of those sections of "The Analysis of Steel-Works Materials" by Brearley and Iffotson which treated of the analytical chemistry of the raw materials and finished products of ferrous metallurgy, including refractories, slags, fuels, boiler feed water and boiler scale.

TESTING OF MOTIVE-POWER ENGINES. Second edition. By R. Royds, head of motive-power engineering department, Dundee Technical College. Pp. 392; 193 illustrations. London and New York: Longmans, Green & Co., 1920. Price \$7.50.

Detailed information is given in regard to the testing of: Locomotives, motor cars, etc.; steam engines and steam turbines; boilers; condensers and air pumps; internal combustion engines; gas producers; refrigerating equipment; air compressors; fans and blowers; water turbines and pumps.

BENZOL—ITS RECOVERY, RECTIFICATION AND USES. By S. E. Whitehead, F.C.S. Pp. 209; 65 illustrations. London: Benn Bros., Ltd., 1920. New York: D. Van Nostrand Co. Price \$5.

Experience gained during the war in the extraction of benzol from coal gas has been made available by Mr. Whitehead in the hope that the process may be made commercially attractive and profitable even in peace times. Careful consideration is given to the processes, equipment, operation and control methods used in the extraction of benzol from gas, the debenzolizing plant and the rectification plant. The chief uses of benzol and its products are treated briefly.

RUBBER MANUFACTURE. By H. E. Simmons, professor of chemistry, Municipal University of Akron, Ohio. Pp. 149; 55 illustrations. New York: D. Van Nostrand Co., 1921. Price \$4.50.

This book gives a general view of the geographical, physical, chemical and mechanical factors which make up the modern rubber industry. Topics treated include: Sources of crude rubber; colloids in relation to rubber; methods of coagulating the latex; theory of the constitution of rubber; synthetic caoutchouc; chemical and physical testing of crude rubber; manufacture and use of inorganic fillers, organic accelerators and rubber substitutes; vulcanization theories; reclaiming rubber; preparation of crude rubber for manufacturing; principles of compounding; chemical analysis of manufactured rubber; physical testing of compound samples. A description of the rubber laboratory equipment at the Municipal University of Akron is given in an appendix.

PAMPHLETS

THE COPPER DEPOSITS OF THE SEVEN DEVILS AND ADJACENT DISTRICTS, by D. C. Livingston and F. B. Laney. Bull. 8 published by the Bureau of Mines and Geology of the State of Idaho at the University of Idaho, Moscow, Idaho.

REFRATORIES FOR ELECTRIC FURNACES has been published by the Electric Furnace Assn., Niagara Falls, N. Y. This book contains the papers and discussions at the Columbus meeting of the Electric Furnace Association, Oct. 6, 1920.

THE FEDERAL WATER-POWER ACT is the title of a 40-page pamphlet published by Black, McKenney & Stewart, engineers, Washington, D. C. It contains a brief history of water-power legislation, a topical synopsis of the federal water-power act and a copy of the act itself.

Capital Increases, Etc.

THE SIMPSON CLARK GLASS CO., 164 West Randolph St., Chicago, has filed notice of capital increases from \$75,000 to \$100,000.

THE ALLIED OIL CORP., 15 East Fortieth St., New York, N. Y., has filed notice of increase in capital from \$12,500,000 to \$16,000,000.

THE LOS ANGELES SOAP CO., Los Angeles, Cal., has filed notice of increase in capital from \$250,000 to \$1,000,000.

THE NATIONAL BRASS CO., Grand Rapids, Mich., has filed notice of increase in capital from \$225,000 to \$450,000.

THE AMERICAN AGRICULTURAL CHEMICAL CO., 2 Rector St., New York, N. Y., manufacturer of fertilizers, etc., has arranged for a bond issue to total \$30,000,000.

THE ALLIED CHEMICAL & DYE CORP., New York, has filed notice of reorganization, to operate with an active capital of \$113,043,675 and preferred stock \$97,326,400.

THE KOKOMO OIL CO., Kokomo, Ind., has filed notice of increase in capital from \$15,000 to \$275,000.

THE FEDERAL CEMENT TILE CO., 110 South Dearborn St., Chicago, Ill., has increased its capital from \$150,000 to \$600,000.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters will be at the Hotel Rochester.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon April 26 at Rochester, N. Y., for luncheon.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NATIONAL PETROLEUM CONGRESS is meeting at the Hotel Baltimore, Kansas City, Mo., March 22 to 25.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP & PAPER INDUSTRY will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, N. Y., April 11 to 14.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: March 25, Society of Chemical Industry; April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Let's Go After

"Two Per Cent for C.W.S."

THE third annual Chemical Warfare Service dinner, which will be held during April, should be the occasion not only for renewal of many friendships but also for vigorous action in the interests of this service. "The gathering of the clan" will give ideal occasion upon which to organize the effort which must be made if chemical warfare is to receive the attention it deserves. And upon that occasion we suggest that some organized effort be started to obtain from Congress "Two Per Cent for C.W.S."

Chemists and engineers in common with other civilized members of the American people desire and will strive for that time when extensive armed preparedness may not be essential. In keeping with this thought it would be difficult to get any large number of chemists who would support the idea of tremendous appropriations for chemical warfare as such. However, chemists and engineers are practical, sensible people rather than idealists and they realize that some military effort is essential without regard to our ideals for international relationships of the future. Moreover, they insist that in this plan must be included a reasonable provision for so essential a branch of the military as chemical warfare. In other words, they can be counted upon to line up unanimously in support of the slogan which we suggest, "Two Per Cent for C.W.S.," that is, provision of approximately 2 per cent of the Army appropriation for this branch of the service.

It takes no argument to convince chemists that gas masks and offensive gas material are as essential to the infantry, the cavalry and the artillery as knapsacks, saddle bags or guns. Without adequate protection against enemy gas attack all of the combatant branches of an army may be helpless. Without gas to shoot against an enemy they are as inadequately equipped as if outfitted with flint locks or popguns. It is only common sense, therefore, to provide a reasonable percentage for chemical warfare out of any appropriation, however large or small it may be in total. And certainly no one can dispute that 2 per cent is unreasonably large, yet this is all that is deemed immediately essential for C.W.S.

In national affairs even more than anywhere else the American people "Let George do it." With respect to the Chemical Warfare Service this policy is no longer safe, for continuation of such plan by the chemists and the chemical industries of the country will inevitably mean a shortsighted inadequate attention to its needs. At the forthcoming dinner we suggest that some official "George" be selected; not one man but a group of men, who will make it a part of their business to sell the big idea of gas defense and offense to those who must be convinced before these military activities will be adequately provided for. If the idea can be sold as it

should be, chemical industries will profit tremendously and the chemists of the country can rest assured that properly planned organized effort of their science will be feasible in case the unfortunate possibility of actual hostilities upon a large scale should again be met by this country.

The researches of chemical warfare are providing much information upon fundamental problems in organic industrial manufacture. Phosgene, chlorpicrin, chloracetic acid and dozens of other important compounds could be named as products of which we will know much more as a result of these studies. Also the theory and the practice of gas absorption and adsorption are being studied in a way that will tremendously interest many other industries. Activated charcoal, the well-known product of chemical warfare investigations, is already proving itself of an industrial value far beyond the total cost of the chemical warfare investigations, and many more such worth while results of this sort of activity can well be expected.

The time for action is at hand, for during the next three months Congress will be called upon to make provision of funds for the Army for next year. Obviously there is no time to delay. Moreover the policy thus fixed for the coming year will be of vital importance for several years to come, since any interruption in the essential research or development program at this stage would double the difficulty and multiply many fold the cost when the work is renewed at a later time. Everyone interested—and what chemist is not so concerned?—must bring his influence to bear immediately.

CHEMICAL & METALLURGICAL ENGINEERING has no hard and fast organization program to suggest. Let the discussion of all those who have been intimately associated in this branch of the service guide in this matter. But as chemists and as industrial men of common sense, let us no longer stand by unorganized in the support of chemical warfare. We have done only a small fraction of what we can and should do. Let us formulate some program which will have as its sole object the fostering for a few years to come of this important idea, "Two Per Cent for C.W.S."

An Unwise

Immigration Measure

THE Dillingham immigration bill, which was killed by a pocket veto of President WILSON in the closing days of his administration, is likely to be revived at once by the new Congress. This measure is decidedly unwise. It prescribes an artificial limitation of immigration to 3 per cent a year of the number now in the United States of the same country of birth. Thus, irrespective of anything else, the proportions of foreign born to be admitted are fixed by the numbers now in the United States, as if there were any virtue in the present proportion.

Getting bills through Congress is usually a very practical question, involving the finding of arguments that will go down and of securing enough votes. The argument of assimilability, on which alone a percentage like that of the Dillingham bill can be based, is quite superficial. It assumes in fact that all races are alike in quality of assimilability, the quantity of possible assimilation being this constant factor multiplied by the number of the race now in the country. We say "race," though as a matter of actual fact the Dillingham bill ignores race and refers simply to country of birth.

Several very practical and important objections to the Dillingham immigration measure were presented to President WILSON on March 1 in a brief by the Inter-Racial Council, with headquarters in the Woolworth Building, New York City. These need not be referred to here. Readers of this journal will find their own reasons for opposing such a bill. This country needs labor. It is rich in natural resources and commands much capital that seeks investment if it can secure a proper return. The country has almost unlimited capacity to employ labor. It will be made more prosperous, not less prosperous, by being given a greater supply of labor. The present industrial depression is due largely, not to there having been too much labor, but to there having been too little labor obtainable for a reasonable sum.

A survey of the flow of immigration in the past illustrates the absurdity of the Dillingham limitation to 3 per cent of the number of persons of a given country of birth now in the United States. From period to period the character of our immigration has changed. Long ago there were the Irish, who constituted the "paddies" of a couple of generations ago, and very useful they were. Successively there has been a flow from one country or another, in a sort of rotation. This natural selection resulted in men whose services were least in demand in their native country coming here where work was ready for them. What we want is that work should be done and we should admit those who are most ready to work. Any legislation framed along this line, if additional legislation is necessary, will be welcome.

One naturally asks himself who is back of this move embodied in the Dillingham bill. The accepted view is that it is "the labor interests." That is particularly curious, seeing that organized labor considers itself skilled, while immigrant labor is unskilled. In almost every undertaking there is both skilled and unskilled labor required. The more easily the unskilled part of the work can be done the more room is afforded for the employment of skilled labor. Does the plumber wish to force conditions whereby he will be obliged to dig ditches part of his time, or the bricklayer wish to become his own hod carrier? Apparently labor leaders cannot rid themselves of the fallacious view that there is precisely so much work to be done, that this work will be done, no matter what, and that if the supply of labor is restricted the total paid out for doing this work will be correspondingly increased.

The Dillingham bill, or such other measure along the same line as may be brought forth in the new Congress, should be vigorously opposed. If additional immigration legislation is requisite, a properly thought out plan should be devised. The argument for the Dillingham measure is specious and superficial, while the objections to it are numerous and fundamental.

A New Gateway To Chemistry

THE address of Dr. IRVING LANGMUIR at the anniversary meeting of the Chemists' Club on March 17 marks a milestone in the history of chemistry. Given a working hypothesis of the structure of atoms, and the path is straightway made clear for chemistry to become a deductive science. Our readers may remember a popular introduction to the consideration of the Langmuir Postulates published in this journal on July 16, 1919. The theory is based on the work of G. N. LEWIS in regard to the so-called cubical atom with that of other savants, co-ordinated and carried on by Dr. LANGMUIR to the state of a working hypothesis. The author makes abundant acknowledgment to the various contributors who have preceded him in the field.

Chemically speaking, the postulates were reasonable, but from the standpoint of physics the objection was raised that the proposed circumscription of electrons to restricted positions was impossible. The theory of BOHR, which has found favor from the standpoint of physics, in which the organization of electrons about a positively charged nucleus might be likened to a solar system, does not aid the chemist. Now Dr. LANGMUIR has succeeded in harmonizing the two theories, so that the developed hypothesis is plausible to the physicist while illuminating to the chemist.

The prospective results of new study with the aid of this enlightenment are amazing. Whereas we have long been engaged in the study of intramolecular phenomena, this opens up the intra-atomic field. It gives us a basis for the computation of the forces emanating from within the atom, so that the perplexing subject of valency may be explained and even valency itself calculated. It offers a reasonable proposal of how each atom is composed, and intimates not only its configuration but even describes the fields of force that surround it within the molecule group. It does not tell how atoms may be broken down, although it may even indicate the way along which such a consummation may be reached—none too soon, let us hope; for we are not good enough to wield such power as yet. But with such a working hypothesis as Dr. LANGMUIR presented, with the structure of each atom agreed upon, with the component forces emanating from every atom in a molecule duly computed, then we should be able to predict the physical qualities of a compound before it is synthesized. It brings within sight the dream of the physical chemist to reason out reactions from start to finish, and then to confirm them by experiment. It gives us the picture of molecules in three dimensions; it tells us of their design, their conformation, and the forces that play from within and about them, the spectral lines of the material product, its colors, its crystal forms, and its reactions.

The time is growing near when, if we are to maintain progress, we must open up this new doorway into the subject, beginning with the study of the reasons why reactions take place, so that with this as familiar information we may compute more and marvel less at the things that are known. And the more we know the greater will be our sense of the unknown infinity beyond us.

Much has already been done along the line of chemical philosophy, but without a definite concept of atomic structures the subject has been difficult, while exposition has been vague. The opening of such a new and illuminating doorway into chemistry will be rather

disturbing to those of us who are of a passing generation, but we are not the persons to be considered.

We have told the story before elsewhere, but it will bear repetition: An assistant of Prof. FRIEDEL in Paris asked him a question in organic chemistry. "Sais pas," answered the professor. "Look it up in Beilstein." After he had been told repeatedly to find in chemical literature answers to the questions that he asked, the assistant inquired of the master whether the instructions were given him for his own benefit, or because the professor did not remember. The old gentleman caught the young man by the arm, led him into the library, and, pointing to the shelves of books there, exclaimed, "Voila! There is all I know. Books are admirable instruments, and we should study them diligently. But why should I encumber my mind with details, making it like a warehouse of unused goods, when all this is available to me? The *general principles*, however, I must always keep alive in my mind!"

That is the way nearly all great chemists understand the subject. It is the true source of enlightenment. It is the way the subject should be taught.

All glory to the few men who, like IRVING LANGMUIR, stand in the watch towers above us, who see the dawn of understanding in these things and point out to us the advancing light!

Green Grass as a Mine for Vitamines

VITAMINES have captured the public fancy. There is the Fat-Soluble A which is found in butter fat, and consequently in milk, in cod-liver oil and in green vegetables, which is necessary for the growth of young animals, to prevent (it is believed) rickets in children, and an unpleasant eye trouble called xerophthalmia in many animals, including the human sort. The Water-Soluble B is needed to prevent beri-beri, which follows a prolonged diet which lacks it, and if taken in inadequate quantities we are subject to boils and skin eruptions, such as acne. The ingestion of food containing it acts as a cure, provided the eruptions are due to malnutrition and not to infection. It is found in milk, in fresh vegetables, in the hulls of rice and some other grains, and in yeast. It is believed also to stimulate the activities of certain glands. The Water-Soluble C is anti-scorbutic. Without it we are susceptible to scurvy, and foods containing it constitute the cure. It is also found in milk, in fresh vegetables and in citrus and other fruits. Unlike types A and B it is very susceptible to heat and its keeping qualities are much frailer unless in an acid medium. The subject is discussed more fully by a member of our staff in the current (March) number of *Harper's Magazine*. The molecular structure of these organic bodies is unknown, but it appears that they are rich in nitrogen, they do not contain phosphorus, and tests are developed to demonstrate their presence.

A good rule to assure ourselves of all the vitamines we need has seemed to be to drink a couple of glasses of fresh milk every day and to eat a good plate of salad. But now come along a group of five from the laboratory of the University of Minnesota, R. ADAMS DUTCHER, C. H. ECKLES, C. D. DAHL, S. W. MEAD and O. G. SCHAEFER, who publish in the *Journal of Biological Chemistry* (vol. 45, pp. 119-32, 1920) a note that is perplexing in regard to the amount of milk needed. "A glass or two" was as near as we dared come to prescrib-

ing. But Messrs. DUTCHER et al. tell us of tests that they made with the cows, giving them a vitamine-poor ration in winter, and with the same grains, but also turning them out to pasture, in summer. The green grass, of course, is vitamine-rich. The result was that "20 c.c. of summer milk was superior in nutritive value and anti-scorbutic potency to 60 c.c. of winter milk from the same cows." We knew there was a difference, more particularly in the anti-scorbutic Water-Soluble Vitamine C, between winter milk and summer milk, but this threefold difference was unsuspected.

In view of the growing need of biological chemistry in organic synthesis, we hope that the study of vitamines will find a more cordial welcome as a subject for research, even in industrial laboratories, than it would have found a few years ago. The Water-Soluble B type may be important in a number of protein reactions.

The Border Lines Of Colloid Chemistry

COLLOID chemistry has been a domain in itself, governed by its own special laws where legislation had influence and otherwise by hypothetical substitutes. Attempts to subject any considerable part of the colloid state to the laws of general physical chemistry are noteworthy undertakings. Perhaps in a century or two from now, when simplified octet chemistry is taught in the grammar schools, the children will study the history of science as well as of political events and each conquest in chemistry will give the basis for a tale as interesting as the conquests of America by the Spanish chevaliers.

Then Dr. JACQUES LOEB will be famous for annexing the amphoteric proteins to the more civilized chemical dominions of the hydrogen ion, the influence of which will be so well understood by both the young and old octet chemists that all explanatory remarks will be superfluous. Even the name hydrogen will perhaps have succumbed to some compound word, indicating nuclei and electrons, their number and positions.

On the basis of our present chemical status, the colloid chemist may pass off the contribution by Dr. LOEB in this issue with the statement that his observations have been limited to dilute solutions and that Dr. LOEB has only confirmed a common belief that any properly dispersed substance in a proper degree of subdivision will obey the gas laws and the others derived from them.

Arguments pro and con by the advocates of either side will take an indefinite amount of time and will not be settled perhaps until one side dies out, as has happened before in the case of phlogiston, fire-water-earth and so on. This will be a task for the theoretical chemists to fight out among themselves. The technologist will readily see where he comes in and will make use of the hydrogen ion concentrations in solving many of his colloidal problems. The gluemaker will wash his product in solution having the right hydrogen potential to give the isoelectric point where glue is insoluble. The water filtration chemical engineer will also receive guidance from the same source and will operate at the isoelectric point of his amphoteric aluminum hydroxide. Large-scale experiments have recently been undertaken at the city water filtration plant of Toronto, Canada, along this line which are proving that Dr. LOEB is right in practice as well as in theory as far as the factor of the hydrogen ion is concerned.

Readers' Views and Comments

The Language of Chemistry

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial in the issue of Feb. 2 on "The Language of Chemistry," permit me to suggest that writers on chemical subjects commonly exercise too little care in expressing their ideas, a fact to which all editors can doubtless attest. Accurate and precise expression when writing on a technical subject cannot be accomplished without the use of technical terms. I am afraid that those who chafe at the use of technical terms are like those who would write *vers libre* or paint Cubist pictures trying to express themselves without having mastered the technique of their art.

The writer sees no possible objection to the correct employment of technical terms. "Pyrolysis" and "pyrolytic," recently suggested by W. A. Hamor, are gems. We need a new word to express the decomposition of alcohols with the formation of water, improperly termed "dehydration"; we also need quite a number of precise terms to replace expressions crudely translated from the German, such as "splitting off" or "splitting out," also "raw" material.

British Research on Automobile Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—Will you pardon me if I point out that an article on the British Steel Research Committee's Report on Automobile Steels in your issue of Dec. 29, 1920, contains a rather serious error in that it describes the 0.35-carbon steel as a *case-hardening* steel? I think that a reference to the report will show that this steel is not described as a case-hardening steel, and is not intended for such a purpose.

The case-hardening steels used by the committee were much lower in carbon, either with or without nickel, as shown in the following tabulation:

	1H	1L	2H	2L	3H	3L	4H	4L

BERNARD COLLITT, F. I. C.

Lincoln, England.

A Question of Therapeutic Value

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your Feb. 16 number is an article "Sulphur Dioxide May Have Therapeutic Value." Shoveling coal may be similarly valuable. During the influenza epidemic of 1918 the working force (over 250) of the American Medical Association was reduced nearly 20 per cent by cases of influenza, but in the engineering department not one of the four men employed there suffered from it. Of course it stands to reason that such evidence is valueless and utterly unscientific be it chlorine, sulphur dioxide or "coal dust."

Chicago, Ill.

PAUL NICHOLAS LEECH.

Bids Bon Jour to Benign Bovine

To the Editor of Chemical & Metallurgical Engineering

SIR:—While Mr. Ford is driving old Dobbin back to the tall uncut the daily press notes that Dr. Earl B. Carr of Melrose, Mass., is likewise herding the gentle cow along the trail toward the never-never land whence the buffalo has disappeared. Through the medium of barnyard chemistry he produces a synthetic milk, using the following formula:

Grind peanuts and oats in sausage grinder, leach with water, add salt and filter. Time required, five minutes.

Can it be that through all these centuries the cow has only been operating as a grinding and leaching plant? If so, the elephants in Central Park, which inhale a great many peanuts daily, may also be made to serve. Are our prize Jerseys and Holsteins to become just family pets along with the Pekingese and poodle? Will the goat which has so long been on the staff of our street-cleaning departments be relegated to the pension list? May we expect a bull movement in September oats and a further scarcity of peanuts in Crackerjack? In other words, and chemically speaking, Mr. Editor, is Dr. Carr's discovery a serious matter?

F. GISTON.

Armour Fertilizer Works

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to my articles on the "Armour Fertilizer Plant" which appeared in recent issues of CHEMICAL & METTALURGICAL ENGINEERING, I note that inadvertently I neglected to acknowledge the courtesy of officials of the Armour Fertilizer Works for the information and illustrations used. The writer is deeply indebted to Austin McGlennon, superintendent of works; to Fred C. Lodge, manager in charge of the Armour Fertilizer properties; and to C. H. MacDowell, president of the company, for releasing this information for publication. I note also that I neglected to state that the excellent piece of construction outlined in these articles was carried out under contract with Dwight P. Robinson & Co., Inc., which built both the acid plant and the general construction in the fertilizer plant. The Armour company engineers directed the placing of the mechanical equipment.

Investigations of the Chemical Literature

To the Editor of Chemical & Metallurgical Engineering

SIR:—May I call your attention to the portion of Mr. Barrows' fine paper on Chemical Literature, headed "Bolton—Select Bibliography of Chemistry" (page 426, CHEMICAL AND METALLURGICAL ENGINEERING, March 9, 1921)?

There is a second supplement to Bolton's Select Bibliography of Chemistry, published by the Smithsonian Institution in 1904. This continues the subject to the close of the year 1902, and contains about 3,500 additional titles.

NATHAN VAN PATTEN.

M. I. T. Library,
Cambridge, Mass.

THE Chemists' Club celebrated the tenth anniversary of the opening of its clubhouse on Thursday evening, March 17. Eight distinguished chemists were enrolled as honorary members, three of whom were present in person and five by representation. Reading from left to right, those seated on the platform in the photograph heading are:

Professor Emeritus Charles F. Chandler, first president of the club; Dr. Edgar Fahs Smith, Dr. William H. Nichols, his Excellency Rolando Ricci, Ambassador from Italy, representing Giacomo Ciamician; Consul General Gaston Liebert of France, representing Prof. Le Chatelier; Dr. Jacques Loeb, Ellwood Hendrick, president of the Chemists' Club; Dr. Irving Langmuir, Consul General Pierre Mali of Belgium, representing Dr. Ernest Solvay; Counsellor John J. Broderick, of the British Embassy; Dr. Alfred Springer of Cincinnati, representing Dr. John Uri Lloyd; Dr. Edward Weston.

President Ellwood Hendrick predicted that the meeting would take its place permanently among the events in the history of chemistry. Dr. Charles Baskerville, chairman of the committee of arrangements, spoke interestingly of the earlier days of the club and then called upon the several members who presented the honorary members as follows:

ERNEST SOLVAY

Presented by Dr. Bernhard C. Hesse

Mr. President, I present Consul General Mali, who stands in the place of Ernest Solvay, founder of the ammonia-soda process, for threescore years a pioneer and leader in industrial chemistry, whose activities have enormously developed the production and use of sodium products over all the world, and likewise have profoundly stimulated dependent and related industries; a leader in the application of scientific study to industrial problems; founder and indefatigable supporter of many institutions devoted to science, to public health and welfare and to the elevation of human intercourse and relations; a source of great strength to his country in her peril, and a shining mark for the vengeance of her despoilers. The members of the Chemists' Club proclaim their admiration and esteem by election to honorary membership.

HENRY LOUIS LE CHATELIER

Presented by Dr. Marston T. Bogert

Mr. President, I have the honor to present Consul General Liebert, as representing our ally the Republic of France,

who will receive for Prof. Le Chatelier the honorary membership which we have in mind to confer upon him. Henry Louis Le Chatelier is professor at Collège de France and at L'Ecole des Mines, member of the Academie des Sciences, for over forty-six years an active, resourceful, fruitful, daring and original investigator of the fundamental principles underlying chemical action and thermodynamics. He has enriched our knowledge with countless facts and with many sound and far-reaching theories based upon them; and he has greatly influenced and enhanced the arts of metallurgy, of electrometallurgy, and of applied chemistry generally. He was called on by his country in her time of stress to bring his profound knowledge and experience to bear upon the solution of problems vital to her preservation and necessary to her progress, and on the return of peace he was honored by her with many prizes and medals. To him the members of the Chemists' Club tender evidence of their profound esteem by election to honorary membership.

GIACOMO CIAMICIAN

Presented by Maximilian Toch

Mr. President, I have the honor to present his Excellency, Orlando Ricci, Ambassador from Italy, who represents Giacomo Ciamician, Senatore del Regno, professor of general chemistry at the University of Bologna, for more than forty-two years an active, ingenious, fruitful and original investigator in pure organic chemistry, applying it to determine the nature and mechanism of the origin of constituents of plants and animals, and the influence therein of sunlight, uncovering many facts which have finally enabled him so to correlate these phenomena that our view of them has become greatly clarified and much firm ground for further and beneficial advance in this most intricate field has been created. The members of the Chemists' Club elect him to honorary membership in recognition of his eminence in science and in appreciation of an associated ally in a holy cause.

SIR EDWARD THORPE

Presented by Dr. Walter S. Landis

Mr. President, I present Sir Edward Thorpe, represented by Counsellor Broderick of the British Embassy. Sir Edward Thorpe was born near Manchester. A student of science at Owens College, the Universities of Heidelberg and Bonn, a brilliant teacher in several colleges in his native land, at the age of three-quarters of a century he is professor of chemistry emeritus of the Imperial College of Science and Technology, South Kensington. For many years director of the Government Laboratories in London, his accuracy of methods of analysis and clarity in their exposition, coupled with a wisdom as to human purposes in the interpretation of law, gave a model for municipal experts in caring for the welfare of his fellow citizens. His delightful biographies of famous chemists are examples of charming literary style for others to study and follow. His Dictionary of Applied Chemistry is an authoritative work, turned to by all seeking full knowledge. His researches in pure chemistry

carried him to the presidency of the Chemical Society of London; his exposition and knowledge of technology were recognized a generation ago by a similar demand on the part of the Society of Chemical Industry, and his breadth of appreciation of all science likewise brought him the vice-presidency of the British Association for the Advancement of Science and the Royal Society. His eminence as a scientist, technologist and author, commanding several languages, for he had a large personal acquaintance with savants of foreign tongues, burdened him with honorary and corresponding memberships in numerous scientific, literary and philosophical academies and societies of other lands. Many times doctored, this Fellow of the Royal Society will long remain a teacher of power, even to many who may never hear his voice. We honor ourselves in electing him to be one of that limited number to whom the Chemists' Club can pay such tribute.

JOHN URI LLOYD

Presented by Victor G. Bloede

(Owing to the serious illness from pneumonia of Dr. Lloyd, he was represented by Dr. Alfred Springer of Cincinnati.)

Dr. John Uri Lloyd was born in New York State. He was a student of science, trained in a severe school of experience in Kentucky. He rose to the professorship of chemistry in the Cincinnati College of Pharmacy and became the president of the American Pharmaceutical Association. By his investigation in phytochemistry, especially applied to medicine, he created new knowledge of alkaloids, glucosides and the physiological variations in reactions of drugs, especially as colloids. A graceful and imaginative pen has augmented his contributions to scientific literature and perpetuated his close and accurate study of the dialect, superstition and folklore of the Blue Grass country. His "String Town on the Pike" alone has aroused interest in chemistry and given pleasure to a world of readers. He, with his brother, has handsomely housed one of the most complete libraries of botany and chemistry in the world, permanently endowed it, and given it in perpetuo to the city wherein he struggled as a youth, conquered as a strong man and now resides, surrounded by the love and esteem of his fellow men. Over threescore years and ten find him still active in the laboratory and public affairs. Numerous honors have come to him and are deservedly his. To them the members of the Chemists' Club take this, their best means, of adding appreciation of his diligent and fruitful labors for human welfare and happiness.

WILLIAM HENRY NICHOLS

Presented by Prof. Wilder D. Bancroft

Mr. President, I have the honor of presenting in person William Henry Nichols, for more than fifty years successfully engaged in those branches of industrial chemistry of fundamental importance to the development of our country, at many places and in every section of this continent; a firm believer in the application of science to industry and always its consistent follower in practice; a stanch and helpful leader and supporter in securely expanding the study of chemical science, research and application in all branches of our educational system; far-sighted in the promotion of international understanding among chemical associations and chemists and for many years with rare patience and discernment creating and fostering opportunities for scientific, technical and social co-operation among the chemists of the United States to the permanent benefit to all. His constructive capacity carried him to the presidency of the American Chemical Society, of which he was one of the founders. His world-wide recognition brought the presidencies of the Society of Chemical Industry and Eighth International Congress of Applied Chemistry. Among the numerous honors and distinctions which have come to him, we, the members of the Chemists' Club, desire to include our appreciation of his great services on behalf of science, business and the welfare of mankind, by electing him to honorary membership.

EDGAR FAHS SMITH

Presented by Dr. Charles L. Reese

Mr. President, I have the honor and take great pleasure in presenting Edgar Fahs Smith, again president of the American Chemical Society after a lapse of twenty-five years; one to whom that Society owes much for devoted and self-forgetful service in its pioneer days; connected with the University of Pennsylvania as educator and administrator for over forty years; a scientist whose researches have covered widely separated fields in electrochemistry, the rare

earths, and atomic weights; author of standard texts on electrochemistry, as well as translator of foreign texts; a historian who adds to a charming literary style the painstaking accuracy and attention to detail which have made him a brilliant teacher and scientist. To the innumerable evidences of esteem and affection on the part of students, colleagues and citizens, we, the members of the Chemists' Club, desire to add ours by his election to honorary membership.

EDWARD WESTON

Presented by Dr. Frederic G. Cottrell

Mr. President, I present Edward Weston, of English birth, for over fifty years an American chemist, physicist and inventor; a scientific investigator of absolute integrity, he has brought to the solution of physical and electrical problems the chemist's point of view. He has been an early worker in the electroplating field, he perfected the dynamo for use in that art; is inventor of the recently rediscovered flaming arc; was one of the pioneers in the development of the incandescent lamp and filament. He is the inventor of standard electrical measuring apparatus. This work involved detailed and long-continued researches on alloys, and the results have led to entirely new views on the nature of metals and non-metals. A wise counsellor in the affairs of the Chemists' Club, the members elect this friend and scientist to honorary membership as an evidence of affection and esteem.

Chemical and Physical Behavior of Proteins

BY JACQUES LOEB

Life is so completely linked to the chemical and physical properties of proteins that the knowledge of these properties must precede the attempt at unraveling the dynamics of living matter. The modern concepts of colloid chemistry have been used to supply this knowledge, and foremost among these concepts is the idea that the reactions of colloids in general and proteins in particular are not determined by the purely chemical forces of primary valency, but by the rules of adsorption; and that the influence of electrolytes on the physical properties of proteins is due to an alteration in the degree of dispersion or in the degree of hydration of the protein particles. The speaker has reached the conclusion that these views are based on a methodical error, so far as the proteins are concerned—namely, on the failure to take into consideration the hydrogen ion concentration, which happens to be the chief variable in the chemistry and physical chemistry of proteins. When this variable is duly considered, it is found that the laws of classical chemistry account for both the chemical and the physical behavior of the proteins.

ISOELECTRIC POINT

Proteins are amphoteric electrolytes the chemical behavior of which depends on the hydrogen ion concentration of the solution. When the hydrogen ion concentration exceeds a certain critical value—which is termed the isoelectric point of the protein—the protein can combine only with anions, forming salts of the type of gelatine chloride, sulphate, etc., according to the nature of the acid added. When the hydrogen ion concentration is below this critical point, the protein can form metal proteinates—e.g., Na gelatinate, Ca gelatinate, etc. At its isoelectric point, a protein can combine with neither anion nor cation. The natural method of freeing a protein from ionogenic impurities consists, therefore, in bringing the protein in powdered form to its isoelectric point and washing it with cold water.

STOICHIOMETRICAL RELATIONSHIPS

The proof that the proteins combine by the purely chemical forces of primary valency and in strictly

stoichiometrical proportions with acids and alkalis is furnished by the titration curves. If we add different acids to an isoelectric protein, we notice that in order to bring a protein solution to a definite p_H —e.g., 3.0 or 2.5—exactly three times as many c.c. are required of N/10 H_3PO_4 as of N/10 HCl or N/10 HNO_3 ; while equal numbers of c.c. of N/10 H_2SO_4 and of HCl are required for this purpose. When we titrate with alkali, we find that exactly as many c.c. of N/10 $Ca(OH)_2$ or of $Ba(OH)_2$ are required as of N/10 $NaOH$ or KOH . These and many similar experiments leave no doubt that acids and alkalis combine with proteins according to the purely chemical forces of primary valency. The proof has been furnished not only for gelatine but also for crystalline egg albumin and for casein.

It follows from these experiments that the anions of weak dibasic or tribasic acids combine with proteins in the form of monovalent ions. Thus the anion of gelatine phosphate is the monovalent anion H_2PO_4 and not the trivalent anion PO_4 ; while in the case of gelatine sulphate the anion is the divalent SO_4 ion.

PROPERTIES A FUNCTION OF HYDROGEN ION CONCENTRATION

These facts furnish the clue for the understanding of the influence of ions on the physical properties of proteins. Before these experiments were made it was customary to express the effect of ions on the physical

while the nature of the ion is of no significance. Thus gelatine chloride, nitrate, tartrate, succinate, citrate and phosphate have the same osmotic pressure, the same viscosity, the same amount of swelling (at the same hydrogen ion concentration and the same concentration of originally isoelectric gelatine), for the reason that in all these cases the anion with which the protein is in combination is monovalent. The osmotic pressure, swelling and viscosity of gelatine sulphate are, however, considerably lower than those of gelatine chloride of the same p_H and the same concentration of gelatine, for the reason that the SO_4 ion in combination with the gelatine is bivalent.

The fact that only the valency of an ion influences the physical properties of a protein, while the nature of the ion is of no significance (unless it causes a constitutional change in the protein molecule), is the crucial point in the interpretation of the influence of ions on the physical properties of proteins; since this fact suggests that this influence depends on simple equilibrium conditions and not on a change in the protein, such as hydration or degree of dispersion.

When increasing quantities of the same acid are added to isoelectric protein—e.g., a 1 per cent solution of isoelectric gelatine—the values for osmotic pressure, swelling, viscosity, first increase until a maximum is reached (at a p_H varying for the three properties between 3.6 and 3.0) and drop again with a further increase in acid added. Colloid chemistry explains such variations on the basis of variations in the degree of aggregation of the particles or of variations in the degree of hydration of the protein particles. When a neutral salt is added to a protein solution, the osmotic pressure, swelling and viscosity drop, and this is also ascribed to a depression in the degree of dispersion or hydration of the protein particles.

THE DONNAN EQUILIBRIUM

Recent investigations have led me to a different view—namely, that the influence of valency, hydrogen ion concentration and the addition of salt on the physical properties of proteins find their explanation in a field entirely foreign to colloid chemistry—namely, to a peculiar equilibrium condition the theory of which was worked out by Donnan. Donnan¹ has shown that when we separate two salt solutions by a membrane which is impermeable for one of the ions while permeable for all the rest, a peculiar equilibrium results at which the distribution of the ions on the opposite sides of the membrane is unequal. It is immaterial whether the ion which cannot diffuse through the membrane is a colloid or a crystalloid. Procter² made use of this Donnan equilibrium to prove that the swelling of solid gelatine chloride is an osmotic phenomenon which can be explained quantitatively on the basis of the Donnan equilibrium.

I started in my investigations with a measurement of the potential differences which exist between a 1 per cent gelatine chloride solution contained in a collodion bag and the surrounding water after osmotic equilibrium is established (e.g., after eighteen hours). It was found that the influence of the hydrogen ion concentration, the valency of the anion in combination with the gelatine and the addition of neutral salt on the

FIG. 1. OBSERVED VARIATION OF OSMOTIC PRESSURE WITH HYDROGEN ION CONCENTRATION

properties of proteins in terms of the so-called Hofmeister series. I have been able to show that these series are based on an error due to the fact that the influence of the variation in the hydrogen ion concentration was overlooked and erroneously interpreted as being the expression of a specific influence of the anion of the acid. If the effect of different ions is compared at the same hydrogen ion concentration, it is found that only the valency of the ion with which the protein is in combination influences the properties of a protein;

M/256	11.2	12
M/128	7.0	7
M/64	4.1	4
M/32	0	0

P.D. was similar to the influence of the three factors on the osmotic pressure, the swelling, and the viscosity of proteins. This in itself would have meant little more than that a fourth property of proteins had been found which varies like the other three properties mentioned, if it had not been for the fact that it was possible to correlate the variations of the P.D. quantitatively with the Donnan equilibrium.

When a gelatine chloride solution is separated from pure water by a collodion membrane, free HCl diffuses into the water, and when equilibrium is established, the concentration of acid in the water (the "outside solution") is greater than in the gelatine solution (the inside solution). This was observed by Procter for blocks of gelatine chloride surrounded by water, and by the speaker when a solution of gelatine chloride was separated from water by a collodion membrane. Procter has shown that on the basis of Donnan's theory the equilibrium is defined by the equation $x^2 = y(y + z)$, where x is the concentration of the H and Cl ions in the outside solution, y the concentration of the H and Cl ions of the free acid in the gelatine (inside) solution, and z the number of Cl ions in combination with gelatine.

If we write the equation in the form

$$\frac{y}{x} = \frac{x}{y + z}$$

$\frac{y}{x}$ becomes the ratio of the concentration of the hydrogen ions inside over those outside. If we assume that the P.D. measured in our experiments was due to the difference in the hydrogen ion concentration on the opposite sides of the membrane, then it would follow from Nernst's well-known logarithmic formula that the P.D. should be equal to $0.058 \log \frac{y}{x}$. Log y is, however, the pH of the inside solution and log x is the pH of the outside solution. Hence, if the Donnan equilibrium

was responsible for the P.D., the observed P.D. should be equal $0.058 (pH \text{ inside minus } pH \text{ outside})$.

CALCULATED AND OBSERVED POTENTIAL DIFFERENCES

It was found that the values for the P.D. calculated on this assumption were in good agreement with the observed values. This left no doubt that the influence of the valency, of the hydrogen ion concentration and of the addition of neutral salt on the variation of the P.D. found its complete qualitative and quantitative explanation on the basis of the Donnan equilibrium.

The close analogy between the influence of pH , valency and neutral salt on the P.D., and on osmotic pressure and swelling, suggested the possibility that these latter properties might also be determined by the Donnan equilibrium. I have calculated on the basis of the Donnan theory the influence of the valency of the anion and of the pH on the osmotic pressure of 1 per cent solutions of gelatine phosphate, chloride and sulphate, and albumin chloride and sulphate, and find the

FIG. 2. CALCULATED VARIATION OF OSMOTIC PRESSURE WITH HYDROGEN ION CONCENTRATION

calculated values agree with the observed osmotic pressures not only qualitatively but practically quantitatively. Thus the curves of the observed osmotic pressure of gelatine chloride and gelatine phosphate (Fig. 1) when plotted over the pH as abscissæ are practically identical and so are the curves calculated on the basis of Donnan's theory (Fig. 2); and, what is more, the calculated and observed curves are, except for two minor variations, practically identical. Furthermore, the observed osmotic pressures for gelatine sulphate are not quite one-half of the observed pressures for gelatine chloride (of the same pH and concentration of originally isoelectric gelatine, Fig. 1). The same

TABLE III. INFLUENCE OF THE HYDROGEN ION CONCENTRATION ON pH INSIDE MINUS pH OUTSIDE AND ON P. D. OF GELATINE-CHLORIDE SOLUTION AT EQUILIBRIUM

difference exists between the calculated osmotic pressures for gelatine chloride and gelatine sulphate (Fig. 2).

Nothing brings out more clearly the difference between the viewpoint of colloid chemistry and the viewpoint of classical physical chemistry than this latter result. In the literature of colloid chemistry SO_4 is called a dehydrating ion which is supposed to diminish the swelling and the osmotic pressure of proteins through a modification of the protein. From our viewpoint the apparent dehydrating effect of SO_4 is merely the consequence of the fact that the valency of the ion with which the protein is in combination modifies the relative distribution of the crystalloidal ions on the two sides of the membrane.

The fact that the Donnan equilibrium is the basis of the variation in osmotic pressure explains also why only the valency and not the nature of the ion has any influence on the osmotic pressure, since the equilibrium equation is the same for all protein-acid salts with monovalent anion. The nature of the anion does not enter into the equilibrium equation.

QUANTITATIVE THEORY IN DEVELOPMENT

If we summarize all these results, we may say that the experiments based on the measurement of the hydrogen ion concentration have proved that the proteins combine with acids and alkalis according to the purely chemical forces of primary valency and in the same stoichiometrical relations in which acids and alkalis combine with crystalloids. They have led to the result that only the valency but not the nature of the ion in combination with a protein affects such physical properties as the P.D. and osmotic pressure and they have further led to the result that this fact finds its explanation in the Donnan membrane equilibrium. Moreover, it was possible to show that the influence of the hydrogen ion concentration on the P.D. and on the osmotic pressure of protein solutions can also be accounted for not only qualitatively but almost quantitatively by Donnan's theory of membrane equilibrium. Procter's experiments and some of the writer's experiments which are not yet complete suggest that the influence of the hydrogen ion concentration and of the valency of the anion on the swelling of gelatine-acid salts may possibly be explained in the same way. The classical laws of general and physical chemistry therefore furnish us with a quantitative theory not only of the chemical behavior of proteins but also of at least some of the physical properties.

Future Developments of Theoretical Chemistry

BY IRVING LANGMUIR

During these ten years that the Chemists' Club has been in this building, of course every chemist knows that great changes have taken place in his science. These are not only changes brought about by the great war, resulting in the stimulation of the chemical industries, but the theoretical work that has been done in chemistry and physics during these years has already had an important influence on theoretical chemistry, and will have an increasing effect as time goes on.

When we look back over the development of science and realize what important applications are made, for example, of the work of Faraday, in electrochemistry, and of Faraday and Maxwell in electrical engineering, and consider that the same kind of thing has happened

already in some fields of chemistry and must happen repeatedly in the future, we have to value very highly the purely scientific pioneer work.

CONCEPTION OF THE ATOM FROM THE ELECTRON ASPECT

During the last ten years a new viewpoint regarding chemical phenomena has been developed. This is the outgrowth of the work of Sir J. J. Thomson and his school. The discovery of the electron occurred only a little over twenty years ago. Up to ten years ago its applications were limited mainly to physical problems, discharges through vacua, conductivity through gases, radioactivity, X-rays, and so on. But beginning about 1911 this began to have deep significance to the chemists, because it gave definite knowledge of the constitution of the atom; and the atom, after all, to the chemist is the most fundamental thing that he has to deal with. If he understood the atom, knew how it is built and is held together, his science then would become a deductive science, it would become like mathematical physics, where from fundamental principles and rigorous reasoning the results of numberless experiments can be predicted with high precision.

THE NUCLEAR ATOM OF RUTHERFORD AND BOHR

About 1911 Rutherford proposed the theory of the nuclear atom, viz., that the atom has a nucleus of positive electricity at its center, and that the electrons are arranged in space about the nucleus.

In 1913 Bohr gave this theory a very definite form, a form which has been extremely valuable and stimulating, by assuming that these electrons are rotating in circular or in elliptical orbits about the nucleus. He also brought in a new element into the theory of atomic structure, the quantum idea, which was derived from the theory that Planck developed in 1903. That is, Bohr assumed that the energy of motion of electrons is determined not only by the ordinary laws of motion, such as Kepler's laws (like planets moving around the sun), but also by a condition which we call a quantum condition, that the angular momentum of the electron about a nucleus shall be a certain multiple of a definite unit. Thus, of all possible orbits consistent with the ordinary laws of orbital motion, only those must be selected which fulfill also these quantum conditions, so that instead of having an infinite number of possible orbits, you have a definite or discrete number of orbits. This quantum theory greatly simplifies the problem, makes it definite, whereas otherwise it would be indefinite.

Now this idea of Bohr has proved of extreme value. For the case of the hydrogen atom he has given us a picture which has been satisfactory quantitatively, that is, it gives us precisely, with an accuracy something like one part in two hundred thousand, nearly all the lines in the spectrum of atomic hydrogen. It has predicted new lines of helium, showing that certain lines which were thought to be lines of hydrogen were really lines of helium. It has shown that these new lines of helium should be slightly displaced from the positions of certain lines of hydrogen, and shown that this displacement is accounted for quantitatively as the effect of the difference in the atomic weight of helium and hydrogen. The theory in its later forms has also shown that these lines, which at first were thought to be simple lines, really have a finer structure; that is, with higher resolving power they can be shown to consist of two or three lines, and the displacement of those

lines from one another is given exactly by this theory. Such remarkable results certainly indicate that we are on the right track in dealing with spectral problems from the quantum point of view.

Then besides this work of Bohr we must consider the work of van den Broek and Moseley, who developed the idea of atomic numbers, that the number of charges on the nucleus is the same as the ordinal number of the element in the periodic table, giving us a clear picture of what the periodic table means from the chemical point of view. Of equal importance to the chemist is the work of Bragg on the structure of crystal by the X-ray method, which has given us definite knowledge of the arrangement of atoms in crystals, which in turn has revolutionized our ideas of valence, showing that in sodium chloride each chlorine is surrounded by six sodiums, and each sodium by six chlorines; that there are no molecules in sodium chloride crystals in the ordinary sense. All those things have come within the last ten years.

DEDUCTIVE CHEMISTRY

And these things mark the beginning, I believe, of a new chemistry, a deductive chemistry, one in which we can reason out chemical relationships without falling back on chemical intuitions. Chemical science in the past has been in a way like biology, botany, geology and so on, in which we deal with general relationships, where we cannot express results quantitatively. We have had, of course, certain fundamental quantitative laws, thermodynamic laws, laws of combining multiple proportions, for example; but although these have been of great importance, they have been capable of accounting for only an insignificant proportion of chemical phenomena.

Now, if we look ahead what do we see as the most probable development in purely theoretical chemistry during the next few years? I believe the field of atomic structure will dominate theoretical chemistry, because a knowledge of atomic structure will enable us to deduce the chemical and physical properties of atoms and molecules.

I have spoken of chemical intuition. The organic chemist of experience knows what the properties of a compound that he has not yet made are likely to be. He has an idea what the color of a certain dye is going to be before he makes it. He tries to make a dye of a certain color. He tries to make a substance which will have certain medicinal properties, and very often succeeds.

Now it is almost impossible to explain the methods by which those results are arrived at, for example, to a physicist. They are not exactly deductive methods; they are more or less intuitive methods, based on large experience, experience which cannot be summarized in a few words, but results in a kind of feeling, a "hunch," that certain results will follow. Now the chemist has accomplished wonders by just that kind of method. Those outside of the field of chemistry do not sufficiently appreciate the value of this method. For instance, the physicist usually does not have much faith in theories of valence. He sees that there are varying values given for valence, and he does not see how reliable predictions of the properties of new compounds can be made on such a basis. But the chemist values those more or less indefinite ideas more highly, and knows how to discount them where needed. He knows that he must not always take the valence of

nitrogen as 3; he must use his judgment in interpreting and making his predictions.

Now the question arises, can this chemical intuition be supplemented by anything which is more powerful? Can we derive with much more precision and certainty, what the properties of compounds are going to be before they are made? Can we tell why it is that the compounds that we have already discovered are the only ones that we have observed; why they are the stable ones, why other compounds whose formulas you might write down on paper are not so stable?

THEORY OF VALENCE SUPPLEMENTED

Within the last month or so I have been trying to analyze the theory of valence, which was developed a few years ago by G. N. Lewis and myself; I have been attempting to analyze that theory more from the point of view of the physicist. In attempting to explain the theory of valence, deriving it from conceptions of atomic structure, I have found physicists extremely skeptical as to the possibility of predicting the properties of compounds. I have not found that difficulty with chemists at all, but the physicist has convinced me that there is a real difficulty there which he experiences because he has not the chemical intuition to help him along. He wants the whole story, not just the part of it which will supplement our ordinary chemical knowledge. That is, he will not grant any ordinary chemical knowledge, he wants the basis for all of it. And the viewpoint is an extremely valuable one, and I think is one which we must lay more stress on in the future, if we want to make chemistry a deductive science.

As an example of what I mean, from the theory of valence which I call the octet theory you can calculate by counting up the number of electrons in an atom (which we know very definitely in every case) how many pairs of electrons could be held in common between the atoms in a molecule. Now, G. N. Lewis has shown that each pair of electrons in common is what the chemist has called in the past a chemical bond.

Since you can count up the number of such electrons, you can say that there cannot be more than a certain number of bonds, or in some cases you may say that there cannot be less than a certain number of bonds. There must be a certain number of bonds in the molecule, but that theory does not tell you yet where those bonds must be. For example, if you try to apply the theory to a compound consisting, say, of four chlorine atoms and one carbon atom, your theory tells you there must be four bonds, but it does not say where. Now, to a chemist you do not have any difficulty in saying that you put the carbon atom in the middle and the four chlorines around, and that gives you carbon tetrachloride and that satisfies the chemist and looks simple enough; but the physicist says, why put the carbon atom in the middle? Why not put one of the chlorines in the middle and the carbon off to one side? You see, that is a very important question from the physicist's point of view. If you are not going to assume any chemical knowledge whatever, why should you not put the chlorine in the middle and have the carbon off all by itself on one side, held by one bond?

Well, the chemist says of course the carbon has a valence of 4. But why should it have a valence of 4? So I have been trying to find out what new points of view we want to bring in, in order to make the octet theory of valence much more definite, and to be able to

predict that the carbon must be in the middle and the chlorines around it, when the four bonds are to be placed among those five atoms.

And I found that to do that, all you need is to call upon Coulomb's law, which is simply the law of inverse square attraction and repulsion between positive and negative charges. From that simple, well known law you can supplement the theory of valence to a degree which seems to me to almost eliminate the necessity for chemical intuition in regard to determining what compounds will be stable and which ones will not be stable. You can then readily derive mathematical formulas to calculate the energy of a given molecule. The potential energy of the electrons with respect to the nuclei and of the electrons with respect to each other can be calculated on the basis of any geometrical model. This potential energy determines how much energy it will take to pull those particles apart, and determines the relative stabilities of different kinds of molecules. I believe, although I have not yet made many quantitative calculations, that on the basis of a very few reasonable assumptions regarding the dimension of the models of molecules, we will be able to calculate with considerable precision the heats of reaction of various chemical substances. Qualitatively, as far as I have worked the thing through, you can consider enormous numbers of substances, and figure out immediately which ones will be the most stable. As far as I can see there is a general close agreement, based on the simple conception that the most stable structure is the one in which the total potential energy is a minimum.

Another way of stating that result is simply this, that the most stable arrangement is that in which there is the most uniform distribution of positive and negative particles. The reason that carbon tetrachloride does not have a chlorine atom in the middle and a carbon off to one side is that that would not be anywhere near as uniform a distribution of positive and negative electricity. If you figure out the potential energy it comes out that way. It is nearly as uniform a distribution as one in which the carbon is placed in the centre. You can very readily put this theory in a simple quantitative form suitable for convenient application.

PREDICTING PROPERTIES OF CHEMICAL MOLECULES

A few months ago I had occasion to talk before a body of physicists on the subject of atomic structure, and was discussing this possibility of predicting the properties of chemical substances without definite chemical knowledge, on the basis simply of certain fundamental principles regarding the stability of certain groupings of electrons. From the position of the inert gases in the periodic table, we can take it as a fact that two electrons around the nucleus as in the helium atom, for example, give a very great stability.

Now, accepting that as a fact, the question was what can be deduced from it. I found a good deal of skepticism among these physicists as to what really could be done from such simple assumptions, until finally I proposed to one of the members who was most active in the discussion or criticism of the theory—in a constructive way, however—that he should answer the question himself as to what a physicist could deduce in regard to the properties; I therefore asked him what compounds there would be between hydrogen and lithium, and if he could tell me what the properties of that substance would be, if there is such a substance. He replied that he had no knowledge of any compounds of

lithium and hydrogen; but by applying the fundamental idea that a pair of electrons around a nucleus will form a very stable configuration, and also by using his knowledge of Coulomb's law and other well known electrical laws he was able in a very few minutes to derive these conclusions: That lithium hydride should have a formula LiH ; that it should be a white crystalline solid body under ordinary conditions, a non-conductor of electricity when solid, but if molten should conduct electricity electrolytically, and hydrogen should appear at the anode, which is not where hydrogen usually appears. Now many of the properties of lithium hydride were not known until recently; but G. N. Lewis predicted those facts in regard to the electrolytic conductivity of lithium hydride, and only recently, within six months or so, Prof. Nernst has had published an article on electrolytic conductivity of lithium hydride, showing that the hydrogen is liberated at the anode instead of at the cathode. Those were predicted in this case by a physicist who had never heard of lithium hydride, and doubted very much whether such a thing existed.

FUTURE CHEMICAL EDUCATION

Now I give this illustration to emphasize a point which I believe it is necessary to consider in a discussion of the future development of science, particularly chemistry. As a science like chemistry progresses it becomes more and more complex. We learn more and more facts. We cannot expect every student of chemistry to go through the whole historical development of chemistry and learn all the facts that we have had to learn. The student who is to study chemistry twenty years from now will need to spend much of his time learning the facts that will be discovered during these next twenty years and will not have nearly as much time as we have to study the discoveries of the last 100 years. To cover the ground he will need to be able to deduce a large part of what we now know from a few simple and almost obvious principles unknown to us.

At the meeting of the body of physicists that I referred to a short time ago there was a discussion as to how chemistry should be taught, and it was maintained by one professor of chemistry that the atomic theory should be taught only after all the general chemical facts are known; that is the teaching of chemistry should follow the historical sequence but with Dalton left out. The students should have all the knowledge that chemists had when they got their ideas of atomic structure, in order that the students may realize how useful the theory is as a method of summarizing the results of experiment.

Now it seems to me that is fundamentally wrong. What we must do now is to present to the student just enough knowledge for him to understand and realize the experimental basis for our ideas of atomic structure, and then use that knowledge of atomic structure in order to deduce practically all the knowledge that most of us have on chemical facts. I think that within a few years we will be able to deduce 90 per cent of everything that is in every text book on chemistry, deduce it as you need it, from simple ordinary principles, knowing definite facts in regard to the structure of the atom. If you know your atoms you will know how they will behave when you put them together. Now if you do that, you can cut down the amount of effort on the part of the student to such a point that he can then go ahead and learn the facts that are going to be discovered in the next twenty years, and will not have to

spend his whole course of instruction in learning what we have had to learn.

It seems to me that we must realize that as each science progresses it gets more complex in some ways, but it also gets more simple in other ways, so that you get broader principles, which allow you to correlate great numbers of facts and put them into simple form.

DIFFERENCES IN BOHR'S AND LEWIS'S THEORIES NOT IMPORTANT

How can those things which we know by experience or by a long process of education be made to appear obvious to the future student, on the basis of certain things that he knows about the atoms? Of course, to go as far as we should like in that direction we will need to know a great deal more about the atom than we do now, for there are some serious difficulties at present. G. N. Lewis in 1916 gave us a picture of atoms with the electrons stationary, held in equilibrium in some unknown way. This is quite opposed to Bohr's theory, in which the electrons are rotating about the nucleus, held out by centrifugal force.

Now from a chemical point of view it really makes very little difference whether you have one or the other. It is a matter that is not of vital importance. You can get a large part of what I have been speaking of, general relationships, by merely considering certain broad geometrical factors, such as the arrangements of electrons in a form having cubic symmetry as distinguished from one with tetrahedral symmetry. This distinction does not depend on any knowledge of whether the electrons are in motion or are at rest. All the chemist usually needs to know is how many electrons are there, and how many are held in common between two atoms. Well, they can be held in common possibly by being stationary between them, or they can be held in common by rotating in a circle between the two atoms. It makes no difference to the chemist when dealing with general relationships.

CALCULATIONS OF QUANTITATIVE DATA

But when we want to go further than general relationships, when we want to get quantitative data, when we want to tie down our chemical facts to observations on spectra, if we want to make use of every spectral line—and there are thousands and thousands of lines in the spectrum of iron—if we want to make use of every one of those lines, in order to predict with precision what the properties of the iron atoms are, we have to know quantitatively what the electrons are doing, and therein I think lies the great future in chemistry. Find the laws of attraction and repulsion and motion of the electrons in atoms, as Bohr has done it for the hydrogen atom, and then from the knowledge of those forces be able to predict or calculate the heat of reaction of a substance with the same kind of accuracy.

Now, of course, to begin with we will be quite content with accuracy within 10 per cent; then later within 1 per cent; but I think that the future holds out for us the possibility of being able to predict heats of reaction, densities, all physical and chemical properties of substances, more accurately than we can determine them by direct methods. I think that is coming, and not so very far off. Already in Germany, Born and Landé have calculated the compressibility of the alkali halides from atomic structural data. They have calculated the heats of reactions; they have predicted on the basis of atomic structure what the energy would be, the heat of

reaction in other words, when an electron combines with a chlorine atom; and they struck it right within a few per cent. It was determined experimentally by Foote and Mohler a year later, and the prediction was verified.

Now, when you can predict heats of reaction, vast possibilities are opened up to the chemist. Thus by deductive means, possibly from the spectra of the elements or from certain fundamental facts in regard to the atomic structure, we may be able to get very much further than we can by ordinary experimental methods.

ORBITAL MOTION CAN PROVISIONALLY BE NEGLECTED

The fundamental question in my mind is whether these electrons are moving or are relatively stationary. The evidence of Bohr's theory has seemed to be almost overwhelming that they are moving in orbits. If this is the case the calculation of the properties of substances seems fundamentally extremely complicated, for the astronomer has never been able to work out orbits of even *three bodies* accurately. Just recently I have found that all the fundamental equations of the Bohr theory can be deduced without assuming any motion of the electrons at all. You can get the Balmer series, you can get all the lines of the hydrogen atom with the same precision that Bohr gets; you can get some of the fine structure (not all of it—just how far we may be able to go it is hard to say yet, because this work is only a few weeks old, and Bohr's theory is eight years old). But at any rate it seems to me significant that we can get the outstanding facts of Bohr's theory by one assumption in regard to a law of force between electrons and positive nuclei. If we assume that in addition to the ordinary force that we know of, the Coulomb force of attraction, we have also a force F of repulsion varying inversely as the cube of the distance r

$$F = \frac{1}{mr^3} \left(\frac{nh}{2\pi} \right)^2$$

Here m is the mass of the electron and h is the quantum constant; n is an integer denoting the quantum state of the electron.

Taking that law (which is about as simple a law as you can imagine that would indicate the necessary factors), you find that electrons reach certain equilibrium positions, and in passing from one equilibrium position to another, they would radiate energy in exact accordance with Bohr's theory, and in fact you get precisely the same formulas that Bohr gets, not only for the energy of the atom, but for the distance between the electrons and the nucleus, and the frequency of vibration of the electron about this equilibrium position comes out the same as the frequency that Bohr got for the rotation around the nucleus.

Now it is too early to say that this is proof the electrons do actually have definite equilibrium positions in the atom. It simply affords an alternative way of looking at it. It seems to me that is the most immediate problem for the chemist, to find out whether these electrons are moving or stationary. If they are stationary the problem is a beautiful chemical problem. It is a comparatively simple matter, if you once know the law of force, to find these positions of equilibrium, to figure out where the electrons are in the atomic structures. On that basis the atomic and molecular models that I proposed a couple of years ago could be used almost as they are, with very few changes. That problem, then, is one in which it looks as though we ought to make extremely rapid progress.

On the other hand, if it is a question of orbits, that is going to be a very very difficult problem to work out in detail. But even if it is a difficult problem, there are ways of generalizing, there are ways of getting approximate solutions.

The kinetic theory of gases affords a parallel. The actual phenomena involved in the myriads of collisions between molecules in a gas are of amazing complexity. Nevertheless, by simplifying assumptions such as spherical, hard elastic molecules with attractive forces varying inversely as some power of the distance, it has been possible to account for practically all the properties of gases. Similarly, in the study of chemical relationships, even before we can calculate the exact positions or possible orbits of electrons in atoms and molecules, we may be able to solve enormous numbers of problems by assuming repulsive forces between charged particles, even if these are merely fictitious forces used to replace the unknown centrifugal forces resulting from certain quantum conditions.

In either case, then, whether the atom proves ultimately to be fundamentally static or dynamic, we may hope that chemical relationships and the prediction of chemical and physical properties of compounds can be based upon simple knowledge of atomic structure, and that this knowledge will largely supersede what must now be classed as chemical intuition.

Knowledge of atomic structure thus promises to make chemistry a deductive science, and a science fundamentally simple compared to what it now is.

Pulp and Paper in 1920

The Federal Trade Commission has recently issued a statistical summary of the paper and pulp industry for 1920. The data on the different grades of paper include: Domestic production, shipments and stocks on hand by months for 1919 and 1920; stocks on hand first of year and end of year and total quantity produced and shipped during year, 1917 to 1920 inclusive. Domestic productions, shipments and stocks of pulp are given by grades for 1917 to 1920 inclusive. Import and export figures on pulp and paper are also tabulated for 1917 to 1920.

From this report the accompanying tables have been prepared, showing production of and foreign trade in pulp and paper during 1920.

Production of paper is classified in grades as follows:

Total newsprint includes all *standard news* and special grades of newsprint, but excludes hanging paper, which is shown separately.

Standard news is the principal subdivision of *total newsprint*, being 32-lb. paper used for printing newspapers.

Book includes all periodical paper and miscellaneous grades of machine finished, supercalendered, coated, etc.

Total paperboard includes all grades of board, such as box, straw, chip, tag, press, fiber, binder, leather.

Boxboard, the principal subdivision of *total paperboard*, is shown separately beginning with March, 1920.

Wrapping includes kraft, manila, fiber, and miscellaneous grades such as glassine, grease-proof, etc., but excludes bag paper which is shown separately.

Bag includes paper made into flexible commercial containers such as grocery bags, flour sacks, etc.

Fine includes writings, bonds, ledgers, etc.

Tissue includes toilet, crepe, fruit wrappers, etc.

Hanging includes paper ultimately intended to be

used for purposes of interior decoration, such as No. 2 hanging, oatmeal, tile paper, etc.

Felt and building includes roofing, felt, sheathing and other grades of building paper.

Other grades include a great variety of specialties that do not classify under any of the above captions.

DOMESTIC PRODUCTION OF PULP BY GRADES, 1920

	Production for Year, Tons	Used During Year, Tons	Shipped During Year, Tons	Increase of Production Over 1919, Per Cent
Ground wood pulp.....	1,578,300	1,456,198	131,495	9
Sulphite, news grade.....	843,514	717,986	126,261	17

Chilean Nitrate Exports for 1920

According to figures kept by individuals engaged in the nitrate business, compiled from periodical official announcements, the total exports of nitrate from Chile in 1920 amounted to 60,679,834 Spanish quintals (1 Spanish quintal = 101.4 lb.). The number of Spanish quintals shipped per month were as follows: January, 9,039,452; February, 6,081,230; March, 5,417,956; April, 5,057,414; May, 5,237,182; June, 2,411,158; July, 3,104,021; August, 4,274,873; September, 5,479,125; October, 4,626,940; November, 3,581,938; and December, 6,368,545.

Copper:Nickel Alloys

**Brief Notes on Structure and Properties of Alloys Used for Driving Bands, Condenser Tubes and Coinage
—Various Names and Analyses for Nickel Silver Are Tabulated,
With Notes Upon Their Most Common Uses**

By PAUL D. MERICA

Superintendent of Research, International Nickel Co.

ALLOYS of copper and nickel are undoubtedly among the earliest known to man. Thus Muspratt¹ mentions Bactrian coins containing 77 to 78 per cent copper and 22 to 23 per cent nickel dating from 235 B.C. This composition is almost identical with our present nickel coinage alloy. In spite of their antiquity, the pure copper:nickel alloys have not come into the commercial prominence which their unusual properties should perhaps give them, although the recent war, with its large requirements of these alloys for bullet-jackets and driving bands, has served to stimulate interest in them.

Nickel and copper form solid solutions in all proportions, as may be seen from Fig. 1, which gives the equilibrium diagram of this binary series. In conformity with this type of equilibrium the physical properties of the alloys vary continuously with composition, maximum and minimum values being encountered within the series. Fig. 2 shows the electrical resistivity,² its temperature coefficient,³ the thermo-electromotive force³ and the hardness⁴ as they vary. Throughout the entire range of composition the alloys are ductile and malleable; their tensile strength and hardness reach a maximum in the neighborhood of 40 to 60 per cent of copper. Table I gives typical values of the tensile properties for commercial compositions of copper:nickel alloys in different forms.

Baucke⁵ has shown that small amounts of nickel increase the toughness of copper as indicated by the notch-bar impact test. He obtains the following results on forged and annealed test bars:

Per Cent Nickel	Specific Impact Work in Kg.-M.
Electrolytic Copper	14.1
0.17	20.0
0.31	22.0
1.52	28.0

Even in small amounts nickel decolorizes copper and its alpha alloys. Thus bullet-jacket stock containing 15 per cent of nickel is practically colorless when freshly cut or polished.

Alloys containing less than 60 per cent of nickel are not perceptibly magnetic, but above that percentage of nickel the magnetism of the alloys may readily be detected with a small magnet.

There are several compositions of copper:nickel alloys in common commercial use. The most prominent are:

(1) Two and one-half per cent (2.5 per cent of nickel) cupronickel for driving bands of shells.

(2) Fifteen per cent cupronickel, used largely for bullet-jackets and by the U. S. Navy for condenser tubes

and feed water heaters, containing from 14 to 16 per cent of nickel.

(3) Nickel-bronze, or coinage-bronze, used for baser currency and containing 25 per cent of nickel.

(4) Copper-nickel, containing 50 per cent of nickel, used for remelting in the manufacture of nickel:copper alloys, and

(5) Constantan, used as one element in the construction of thermocouple pyrometers and also as electrical resistance wire, containing 45 per cent of nickel. Their properties will be noted elsewhere in company with other nickel alloys used for special electrical properties.

Of these perhaps the most interesting, in view of its large use during the war, is the bullet-jacket composition commonly known as cupronickel. These alloys are generally made by melting copper in crucibles together with shot or electrolytic nickel following the practice in melting brass and bronze. The metal has a strong affinity for gases and oxygen and before casting is usually deoxidized with from 0.5 to 1 per cent of cupromanganese in order to secure a sound ingot; it may also

be readily deoxidized with magnesium. These ingots are cold-rolled to the size required and annealed at about 700 deg. C.

A striking property of this composition is its greater malleability, as evidenced by the fact that a cast bar 1.25 in. thick may be cold-rolled to 0.040 in. or even thinner, without intermediate annealing. Webster⁶ has determined the effect of cold reductions upon the tensile properties of cupronickel as shown below:

History	Tensile Strength, Lb. per Sq. In.	Elongation in 4 In., per Cent	Reduction of Area, per Cent
Normalized.....	50,000	28	63
20 per cent reduction.....	60,000	5	58
40 per cent reduction.....	70,000	3	56
60 per cent reduction.....	80,000	2	53

A typical analysis and tensile test of bullet-jacket material is as follows:

	Per Cent		Per Cent
Copper.....	85.16	Manganese.....	0.11
Iron.....	0.23	Carbon.....	0.029
Nickel by difference.....			14.47

Tensile strength after cold-rolling to 0.040 in. and annealing, lb. per sq. in. 46,900
Yield point, lb. per sq. in. 22,300
Elongation in 2 in., per cent 35.4

These alloys are also quite resistant to corrosion and are therefore in wide use as Benedict metal for condenser tubes; see U. S. Navy Department specifications 46N1a of 1917. The following values of the tensile properties are typical for this material in tube form:

Outside Diameter, In.	Wall Thick., In.	History	Tensile Strength	Elongation
0.517	0.038	Annealed	43,080	39.0% in 10 in.
0.516	0.036	Light drawn	51,520	8.1% in 10 in.
0.750	0.047	Medium drawn	60,300	4.2% in 8 in.
0.750	0.047	Hard drawn	75,800	2.0% in 8 in.

Bengough⁷ has studied the effect of high temperatures on the tensile properties of a 20 per cent copper:nickel alloy.

This metal is subject to a curious type of intercrystalline brittleness at present insufficiently understood. After annealing it frequently is so brittle that it will bend only a few degrees. Under the microscope it presents the appearance shown in Fig. 3, whereas normal annealed cupronickel has a structure shown in Fig. 4, consisting of an aggregate of grains of copper:nickel solid solution. The intercrystalline appearance in the embrittled metal is rather similar to that which occurs on "burning" nickel and Monel metal. By some (see Thompson and Barclay⁸) this brittleness is considered as being associated with the precipitation of graphitic carbon and on this account manufacturers of this metal aim to keep the percentage of total carbon below about 0.04.

The cupronickel alloys are found not to be subject to corrosion- or season-cracking as are the brasses, bronzes and also the nickel:silver alloys.

The composition used for nickel coinage—i.e., containing 25 per cent of nickel, is a very old one. This material has essentially the color of pure nickel, is hard and resistant to abrasion and corrosion; being softer than pure nickel, it is not so difficult to stamp as is the latter. It is manufactured in much the same manner as cupronickel. It is estimated that the total amount of nickel used in nickel coinage is not over 15,000 tons.

A series of alloys containing copper, nickel and zinc is also of very old origin, having been known in China under the name of packfong, or white copper. The most common name for them at one time was German silver, but since the war the trade has accustomed itself to the term nickel silver. The name "nickelene" has been recently suggested by the non-ferrous nomenclature committee of the American Society for Testing Mate-

⁷J. Inst. Metals, vol. 7, p. 182 (1912).

⁸J. Soc. Chem. Ind., vol. 38, p. 130 (1919).

rials. In France, the name maillechort is used for this series of alloys.

Compositions which are in commercial use are quite numerous; they will vary usually within the following limits: Copper, 52 to 80 per cent; zinc, 10 to 35 per cent; nickel, 5 to 30 per cent.

Particularizing, the compositions of nickel silver in common commercial use in the United States are as follows:

	Nickel, per Cent	Copper, per Cent	Zinc, per Cent	Lead, per Cent
Cutlery and knife stock	15-25	55-65	14-20	Fe $\frac{1}{2}$ -1 $\frac{1}{2}$
Key stock.....	8-18	55-65	15-35	1-2
Jewelers' wire.....	5-25	53-63	25-32	...
Brazing solder.....	8-20	35-40	40-55	...
Watch case metal.....	10-28	55-65	16-30	0-1
Spoon and fork stock..	10-20	57-66	20-30	...
Platers' bars and cores.	5-25	56-70	18-24	...

Nickel silver is marketed in several grades, depending chiefly on the nickel content, high-grade alloys containing about 20 per cent and low-grade ones less than 10 per cent. Abroad, these are called firsts, seconds, thirds, fifths, etc., but in this country are named according to their nickel content (Table II). An idea of the various trade names which have been given to these alloys may be obtained from Table III.

These alloys are largely used as substitutes for silver and as base metals for plated silverware of all sorts, their suitability for both purposes being due to the fact that their color is very similar to that of silver. They are used in the production of a large number of ornamental fittings and stampings for which an attractive finish and resistance to corrosion are desired and also in the form of wire for small springs and for electrical purposes. Their color varies from a nearly white, nickel color with the higher percentages of nickel to a yellowish white color in the compositions of lower grade or nickel content.

As above noted, the compositions of nickel silver used for any specific purpose are quite variable. It will be understood that lead is added when ready machinability is desired (1 to 2 per cent in key stock); however, it is kept out in material which is to be spun or drawn, as it diminishes the ductility of the alloy.

Analyses of two typical compositions of nickel silver follow:

	No. 1, per Cent	No. 2, per Cent
Copper.....	63.03	63.39
Lead.....	None	None
Iron.....	0.12	0.13
Manganese.....	0.037	...
Nickel.....	16.69	18.37
Zinc.....	Remainder	17.98

The alloys are produced by melting copper together with nickel silver scrap in graphite crucibles, adding the nickel and zinc, deoxidizing with from $\frac{1}{4}$ to $\frac{1}{2}$ per cent of cupromanganese and pouring into ingots, which are cold-rolled, with annealing and pickling, into the sheet or strip required, or drawn into wire. The presence of zinc renders this alloy much easier to cast in a sound condition than cupronickel. Annealing is carried out usually at 700 deg. C. in a muffle furnace excluding air.

Copper, zinc and nickel in the proportions used in nickel silver unite to form a single solid solution; these alloys are therefore similar structurally to high and low brass or to copper:nickel alloys, and consist of one (alpha) constituent only. They may be etched with ammonium hydroxide and hydrogen peroxide in the manner used for high brass.

Studies in Colorado Shale Oils

Lighter Hydrocarbon Oil Fractions Found to Be More Saturated Than Heavier Fractions—
Methods Used in Obtaining Data—Graphical Analysis of Distillation Cuts,
Showing Temperatures, Saturations and Specific Gravities

BY ARTHUR J. FRANKS

WITHIN the past few years the American shale oil question as an industry has emerged from its position in nebular speculation and is now being fast recognized, not as a mere potential possibility but as a proximate reality. Realizing the intense scientific as well as popular interest in shale oils, the author is pleased to submit this paper as a small contribution to our knowledge, hoping that it will further accelerate the building of an industry that is rapidly assuming definite form.

This investigation was made for the purpose of studying the general character of the crude oils and their fractions and also the distribution and character of the saturated, unsaturated, sulphur and nitrogen compounds in these fractions. Owing to the great difficulty attending the accurate determination of some of the constituents and the identification of others ordinarily found in mineral oils this paper must be considered as the result of preliminary studies only. More thorough investigations are already planned for the future.

The oils studied were all obtained in the Ginnet retort by low-temperature carbonization of shales found in the vicinity of De Beque, Col. These oils were produced during experimental operation. As the shales were from different strata and the conditions obtaining during the various carbonizations were not always identical the oils must show consequent differences. It was to classify and if possible explain these dissimilarities that the first part of this work was undertaken.

METHODS OF ANALYSIS USED

Since shale oils possess certain inherent characteristics which differentiate them from petroleums, and for other recognized reasons, it was found necessary to depart somewhat from a number of the more or less standard methods of analysis generally used in petroleum technology. In order that the analyses given herein may be of the most value these departures will be given detailed consideration.

Except where otherwise stated the volume of oil taken for a distillation analysis was 500 c.c. A sample of this magnitude yielded fractions large enough for all subsequent investigation. Fractionations were made in 1,000 c.c. Pyrex distilling flasks, except where only small samples were available, in which case a 500 c.c. flask was used. The standard flasks recommended by the United States Bureau of Mines¹ are not suitable for the analytical distillation of shale oils because the high necks, especially when filled with beads, cause excessive cracking of the heavy fractions and great irregularities in the last part of the analysis. Even when proceeding as described above the last oils can escape undue decomposition only by meticulous regulation of the gas flames by the operator. The distillation rate was main-

tained as nearly as possible at two drops per second for the 500 c.c. samples, and at a proportionately lesser rate for the smaller ones. The oils were distilled into 10 per cent fractions, the percentages being expressed by volume. This system of fractionation is superior to that in which the cuts are made on a temperature basis, because the results with the former are more readily and comprehensively represented graphically. Except in one case distillations were carried to complete dryness. All temperatures are given in degrees Centigrade, and are uncorrected for the emergent stem. Bunsen burners were used as a source of heat. The naked flame is required to drive over the last fractions of the oil. Since the gas was often poor and the pressure frequently variable, the temperatures near the end of the distillation sometimes fluctuated more or less. In drawing the distillation curves this was considered and the mean values taken as the true temperatures.

The specific gravities were, in each case, obtained from the Baumé value by conversion with standard tables, and are always expressed at 25 deg. C., which is a convenient and practical basis of comparison. While it is, of course, understood that the ordinary hydrometer is not a very precise instrument for the measurement of specific gravities, it is nevertheless capable of greater accuracy than is possible in the rest of the distillation analysis and is therefore entirely suitable for the present purpose.

SATURATION PERCENTAGE

The "saturation" of crude oils and fractions is that percentage of volume which is not attacked by concentrated sulphuric acid. This is determined in the following manner. A 9.8 c.c. sample of the oil is measured into a 9 or 18 g. Babcock cream test bottle, the smaller size being used when the expected saturation is less than 50 per cent and the larger size when it is more. Twenty c.c. of concentrated sulphuric acid is then added, the bottle is corked, and the mixture simultaneously cooled and slowly shaken until all violent action has ceased. It is then thoroughly shaken for one minute. Concentrated sulphuric acid is then added until the level of the liquid has risen to the neck of the bottle, which is now immersed to nearly its full length in hot water. When the mixture is quite warm it is immediately centrifuged for about two minutes, the centrifuge running at high speed. Acid is then poured carefully into the bottle until its level below the supernatant oil is plainly visible above the lowest graduation mark, and the centrifuging is repeated until a constant reading is obtained. When the 9 g. bottles are used the percentage saturation may be read directly on the bottle. With the 18 g. bottles the readings must be multiplied by 2 to give the correct value. In the case of very light oils the warming of the mixture before

¹Bulletin 125.

*No determination made.

centrifuging is unnecessary and is to be omitted, since there is danger of losing part of the unabsorbed constituents by volatilization. The probable sources of error and the accuracy of the method described are discussed in a publication of the United States Bureau of Mines.²

It has been customary heretofore to determine the unsaturated rather than the saturated compounds in mineral oils, this being expressed as that percentage by volume which is dissolved by concentrated sulphuric acid. The remainder was assumed to be the saturated³ hydrocarbons. But since it is the saturated portion of the oil that is actually measured, and mainly because that part of the oil which is attacked by the sulphuric acid is not necessarily composed entirely of "unsaturated hydrocarbons," it is incorrect to speak of it as such. This error is especially to be avoided in the case of shale oils, since they contain bases and other compounds soluble in sulphuric acid which are not hydrocarbons at all, nor are they even "unsaturated." Therefore the author has discarded entirely this loose expression and uses and recommends the term "saturation" to express that percentage of the oil not acted upon by concentrated sulphuric acid. If it is still desired to express the value of an oil for refining in terms of that percentage which is absorbed rather than

unabsorbed by the acid, then another term, such as "sulphuric acid absorption," should be used, especially for shale oils.

The initial boiling point (i.b.p.) is herein considered as that temperature at which the first drop is seen in the condenser. For oils containing only a small percentage of low-boiling constituents this is more nearly the true boiling point than the temperature at which the first drop is observed in the receiver.

The water is expressed in volume per cent and was determined during the distillation. In cases where more than 1 per cent of water was present the distillation was carried to about 180 deg., the water separated from the light oil and the latter returned to the distillation flask. The fractionation was then carried out as usual.

The coke is expressed in weight per cent of the original oil. The weights of coke were obtained by weighing the flasks before and after the distillation, the differences being, of course, the coke.

The sulphur is given in per cent by weight, and is the average of duplicate analyses which checked fairly well. The method of determination (using nitric acid in the decomposition of the oil) will be described in a subsequent paper.

In Table I are found the analyses of the original crude oils. The data for the distillation analyses are given in Table II, and the saturation of the fractions in Table III.

TEMPERATURE, SPECIFIC GRAVITY AND SATURATION CURVES

All the data are represented graphically by the curves in Figs. 1 and 2 which portray the properties of the

FIG. 1. TEMPERATURE CURVES FOR CRUDE OILS

different oils and their fractions in a very condensed but interesting form. Fig. 1 contains the cut-temperature curves, in which the percentages of oil distilled are plotted as abscissæ and the temperatures as ordinates. Since the boiling point of a complex mixture of homologous or otherwise related compound always rises gradually during a fractionation, the curves representing the distillation should be smooth and free from too sudden irregularities. Great fluctuations must be due to variations in the source of heat, and consequently in the rate of distillation. Hence the curves were drawn with these considerations in view, their paths being through the mean or theoretical values. In Fig. 2 are found the specific gravity and saturation curves, the percentages distilled being again plotted as abscissæ and the specific gravities and saturations as ordinates. Here, as in Fig. 1, the curves are drawn smoothly and strike the mean values wherever fluctuations are marked. In almost every case, however, the curves pass through or very close to the determined points.

Before discussing and interpreting the data from the analyses it is advisable to have more definite information concerning the individual oils other than the general location of the deposits of shale from which the oils were produced. The shales were all crushed to pass a $\frac{1}{2}$ -in. screen before being carbonized.

Oils 1 and 2 were obtained from samples of shale taken from the same deposit, the exact location of which is not known. It is in the vicinity of De Beque, Col., which is the general source of all the shales herein mentioned. Oil 3 was produced from shale found in the "rubber stratum," on the property of the Monarch Shale Oil Co. Oil 3a is a composite of the fractions obtained from the distillation of No. 3. Oil 4 was made from Mount Logan shale which yielded 45.3 gal. of oil per ton. No agitation was used during the retorting of this

charge. Oil 5 was obtained from shale which yielded 38 gal. of oil per ton. The exact location of the shale deposit is not known, since the sample was gathered at the foot of a high cliff. Oil 6 was made from the same shipment of shale as No. 5; however, the condensers were not functioning properly during the process of retorting and a large portion of the light oil escaped condensation. Oil 7 is a composite of ten samples of oil obtained from the secondary condenser, or that section of the condenser in which the light fractions were condensed. Oil 8 is the composite taken from the primary condenser during the same series of operations. Oils 7 and 8 were both produced from the same shale that was used in making oils 5 and 6. Oil 9 was the product of the carbonization of another sample of shale from the rubber stratum.

DISCUSSION OF RESULTS

Little need be said about the temperature curves in Fig. 1, since they are self-explanatory. They are all similar in shape, which shows that the oils differ in degree rather than in character. It is remarkable that all the curves show more or less sharp turning points at about 350 to 360 deg., which represents the temperature interval within which cracking occurs in the end fractions. The cracking begins as low as 300 deg., but is very slight at this temperature as compared to that at 350 to 360 deg., which seems to be the range of temperatures in which certain constituents of the crude oils are unstable. It might be expected that the oils which do not crack are those of a more stable nature. This supposition is substantiated by the curve for oil 3a (already once distilled), which shows a less sharp turning point and a steady rise up to 380 deg., the highest temperature reached by any of the oils. The temperature curves for the other oils tend to straighten out at about 350 deg., showing that the light oils formed by the cracking lower the vapor pressure of the heavy oils, and hence the boiling point fails to rise, and even falls rapidly as the cracking becomes more and more pronounced.

The temperature curves for oils 7 and 8 are of special interest since they demonstrate that it is not possible to condense fractionally the oil vapors with any degree of success. This is obvious because the product from the first stage condensers (oil 7) contains a considerable amount of light oils, while that from the secondary condensers (oil 8) contains more than an appreciable amount of the heavy fractions. These results must, unfortunately, explode the theories propounded by a number of inventors of oil shale retorts.

The specific gravity curves in Fig. 2 substantiate the conclusions drawn from the temperature curves. The similarity in shape of the former is further evidence of the likeness in character of all the oils. The more or less sudden rise at the end of most of the curves indicates a sudden increase in heavy fractions and a decrease in their cracking. This is due to abnormal rises

in temperature near the end of the distillation caused by the overheating, which resulted in attempts to maintain a constant rate of distillation. With more uniform conditions this would not have occurred and the curves would then have resembled the one for oil 3, which is typical for all crude shale oils (from De Beque shales) when properly distilled. However, it was almost impossible to obtain such conditions with the gas that was used as a source of heat. This will be obvious to anyone who has attempted work of this kind under the conditions that are given.

LIGHTER FRACTIONS MOST SATURATED

The significance of the results for the saturation of the different fractions, given in Table III, can be fully appreciated only when studied in connection with the curves in Figs. 1 and 2. The fact that the lighter oils are the most saturated is at once apparent, as well as the generalization that the saturation decreases with increase in boiling point and specific gravity, up to the point where cracking begins. The most remarkable of all the results which this research yielded is now to be noted: the knowledge that the cracking of the unsaturated and unstable oils in the heavy fractions produces lighter oils of higher saturation.⁵ This phenomenon, a stranger to petroleum technologists, occurs in every destructive distillation of crude Colorado shale oils that has been attempted, to the best of the author's knowledge. The general trend of the data seems to indicate that the more pronounced the cracking the greater is the increase in the saturation and the fall in the specific gravity and distillation temperature. This is the inevitable conclusion that must be drawn from the fact that each depression in the temperature curve is followed by a corresponding fall in the specific gravity curve and

FIG. 2. SPECIFIC GRAVITY AND SATURATION CURVES

a rise in the saturation. The consistency of these phenomena has caused considerable speculation and theorizing concerning their causes, but no entirely satisfactory hypothesis has yet been propounded. The only explanation seems to lie in the fact that it is possible to obtain saturated compounds from certain types of unsaturated compounds, such as resins, or in the possibility that the saturated compounds in the crude oil and the thick, heavy fractions cannot be correctly determined. The first suggestion is by far the most plausible;

yet it is difficult to understand how such a relatively small amount of cracking can result in such an increase in saturation as is found in oil 3a over that obtained for oil 3, the gain in saturation being over 100 per cent. Research is now under way at the Colorado School of Mines with the purpose of determining the causes of and factors that influence the phenomena, so no more will be said about it at present. The reader is free to speculate with the data at hand, and can draw what conclusions he will.

The author takes pleasure in giving credit to C. P. Hackett, who made most of the distillation analyses, and to J. P. Bacca, who made most of the determinations for saturation of the fractions. Thanks are also due to Prof. A. H. Low for his valuable criticisms and suggestions.

Corrosion of Soft Metals

The commercial soft metals include aluminum, tin, zinc and lead. It was shown in Scientific Paper 377 of the United States Bureau of Standards that a type of deterioration designated as "intercrystalline brittleness" may occur in lead under certain conditions whereby the metal crumbles to a coarse crystalline powder. The individual grains of this powder retain all the intrinsic properties of lead, but the bond between the grains has been destroyed.

During the past year a series of corrosion tests has been carried on to demonstrate to what extent such deterioration may occur in other soft metals. The intercrystalline brittleness appears to be largely dependent upon the purity of the metal, and in the pure materials used in the test very slight evidence of such deterioration was obtained. A series of stress corrosion tests has been conducted to supplement Scientific Paper 377 and it has been shown that the simultaneous application of tensional stress to a specimen while corrosion is in progress is a powerful adjunct to deterioration by "intercrystalline brittleness." This is of practical importance, inasmuch as lead—because of its great weight—is often subjected to very considerable stress while in service. Thus the tendency to corrode and become embrittled is accentuated.

Canada's Foreign Trade in 1920

Calendar-year figures published in the *Weekly Bulletin* of the Canadian Department of Trade and Commerce show for the Dominion's foreign trade in 1920 an aggregate of \$403,882,150 in excess of 1919 and \$485,847,223 greater than in 1918, last year's total of \$2,639,726,135 comparing with \$2,235,843,985 in 1919 and \$2,153,878,912 in 1918. The share of the United States kept pace with the increasing total trade of the Dominion, forming 55 per cent thereof in 1918 and 1919 and 57 per cent in 1920. On the other hand, trade with the United Kingdom declined, as the following summary shows:

Calendar Years	Total Trade With		
	All Countries	United Kingdom	United States
1918.....	\$2,153,878,912	\$659,442,645	\$1,193,232,897
1919.....	2,235,813,985	626,633,484	1,231,656,516
1920.....	2,639,726,135	574,699,070	1,507,651,094

With imports amounting to \$1,336,921,021, exports to \$1,272,657,442, and re-exports to \$30,147,672, the calendar-year balance of trade against the Dominion was \$34,115,907, contrasted with a favorable balance of \$353,816,759 in 1919 and one of \$333,580,632 in 1918.

⁵Similar results were reported on other shale oils in a paper by C. W. Botkin before the Colorado Section of the American Chemical Society, Nov. 27, 1920, and in a personal communication to the author before this work was undertaken.

Influence of Copper on Some Physical Properties of Iron and Steel

A Number of Ferrous Alloys Were Made and the Physical Properties of Forging, Filing, Grinding, Chiseling and Bending Determined—It Was Found That Copper Caused Iron to Be Red-Short and That Manganese or Chromium Removed This Difficulty

BY E. A. RICHARDSON AND L. T. RICHARDSON

DURING the past several years a somewhat comprehensive study of the corrosion of copper-bearing irons and copper-bearing steels has been under way, for the carrying out of which a number of iron alloys containing copper were made. In the preparation of these alloys for the corrosion tests and supplementary to these tests certain properties of a physical nature were investigated. This was considered necessary, since the commercial value or the actual use to which any rust-resisting alloy can be put will depend to a large extent upon the various physical properties; in fact these properties will determine whether an alloy would be adapted to a general or to only a specific use. The present paper proposes to deal with these physical properties. The results of the corrosion tests have been already presented before the American Electrochemical Society.*

The physical properties upon which tests were made were as follows: Forging, filing, grinding, chiseling, bending.

FORGING

Considering the iron alloys of copper from the general literature, it appears that the forging properties have not been very extensively or thoroughly studied. Although numerous references can be found relating to the effect of copper upon the forging properties of iron and steel, it is a rather surprising fact that the conclusions reached by different investigators are so greatly at variance. However, if one analyzes the results more carefully and divides the alloys into iron:copper alloys and steel:copper alloys, the confusion is not so great. For instance, in five references that were found relating to the effect of copper on the forgeability of iron, four authors^{1,2,3,4} state that copper renders iron red-short, while one⁵ who worked with wrought iron states that as high as 0.50 per cent of copper causes only traces of red-shortness. Hence, in iron at least, most authorities believe that copper is detrimental to the best forging properties.

In the case of steel, on the other hand, out of twelve references only one⁶ states that copper causes red-shortness, ten^{7 to 16} say that in reasonable amounts (0.50 per cent copper or less) copper produces no red-shortness, while one¹⁷ even says that copper when added to steel decreases red-shortness. In addition to this, one of these investigators¹⁴ finds that 0.50 per cent of copper is necessary before red-shortness occurs in steel, another¹⁰ believes that 1 per cent copper is needed, while yet another¹³ states that 4.70 per cent of copper is necessary to produce red-shortness. Moreover, one man¹⁷ draws his conclusions from laboratory tests and another¹¹ from many thousands of tons of bessemer rails

containing copper. In the case of steel the fact seems to be that copper in reasonable amounts does not harm the forging properties.

Hence one would conclude from the published literature that copper when added to iron is more likely to cause red-shortness than when added to steel, and that in steel a certain limit exists above which copper causes red-shortness.

Some years ago, while studying at the University of Wisconsin under Prof. C. F. Burgess, one of the authors made a series of alloys of copper and electrolytic iron and in forging these alloys noted this property of red-shortness. Red-shortness shows itself in a very abrupt change from a forgeable to a non-forgeable state; a piece of copper-bearing iron upon being forged down from a white heat would at first be very soft and could be forged with ease, but as a lower temperature was reached the metal suddenly became brittle and would crumble into many fragments under a few blows of the hammer. The resulting fracture had a granular appearance as if rupture had occurred between the grains. Since the present authors hold that the existence of intergranular material has a great effect upon corrosion, and the phenomenon of red-shortness of copper:iron alloys was known before the alloys were made for the corrosion investigation of which this paper is a part, in forging these alloys especial attention was paid to the hot-working properties.

The composition of the alloys made, together with their forging properties, is given in Table I. The alloys were made by melting commercially pure iron in an electric furnace and adding the carbon-free alloying elements to the molten iron. The forging properties were obtained by heating the ingots to a bright red heat and then forging continuously with a hammer to a black heat, this operation being repeated five to ten times (depending on the hardness of the alloy) before the desired shape and size were obtained. The forgings were then thoroughly annealed and the other properties obtained upon such forged and annealed material.

A study of the forging data given in Table I brings several fundamental facts to light. In the first place, it is evident that very small amounts of copper make metal brittle in forging, but that this property appears only during a certain temperature range and that above or below this range forging can be accomplished. Furthermore, our experience has been that the greater the copper content the greater is this interval of non-forgeability and the more difficulty is encountered in obtaining a satisfactory forging. Thus with an iron containing 4.65 per cent of copper (alloy M) forgings can be made only at very low temperatures and much work must be expended.

This phenomenon is also met with in the hot-working

of a well-known commercially pure iron, which contains copper from 0.03 to 0.04 per cent. The existence of this red-short range has been recognized by the manufacturers of this iron, who advocate that their material should not be worked between the temperatures of about 800 deg. C. and about 1,000 deg. C. Apparently they have never recognized this peculiarity of their product as due to the presence of copper in small amounts, but either have offered no explanation for it or have ascribed it to the well-known transformation of α to β iron that takes place at about this same temperature.¹⁶ Quite recently another explanation has been given for the brittleness of this iron, in which the cause of red-shortness is said to be due to an intergranular film, possibly iron sulphide.¹⁹

The writers agree that this phenomenon of red-shortness is probably due to intergranular material, because the fracture has every appearance of being between the grains. However, we believe that the film which becomes weak in the brittle range is copper or some alloy or compound of copper. The fact that the appearance of the fracture, the method of breaking and the brittle temperature of this commercially pure iron are identical with our copper:iron alloys tends to substantiate this belief. The idea that this structure may have some effect on the corrosion of copper:iron alloys has already been enlarged upon in the paper on corrosion.

Another conclusion that can be drawn from the data which is fully as important as the belief that copper

causes red-shortness is the certainty that this can be removed by the addition of manganese or chromium. This easily explains and reconciles the differences noted by earlier investigators where copper was found to make iron but not steel red-short. Iron contains no manganese and the harmful effect of copper is not removed, while in steel the manganese present is sufficient to do this unless the copper is very high. It also suggests that the forging properties of commercially pure iron could be improved by small additions of manganese or chromium. That this would not impair but would improve at the same time the rust-resisting properties has already been shown in another paper.

To illustrate this combined action of copper and manganese, we may cite alloy N, containing 0.92 per cent copper and 0.32 per cent manganese, which was slightly red-short, while alloy P, containing 0.48 per cent copper and the same amount of manganese, forged at all heats. This suggests that for each percentage of copper a certain quantity of manganese is necessary to eliminate red-shortness.

FILING, GRINDING, CHISELING AND BENDING

These tests are all of a somewhat similar nature. In the alloys made commercially pure iron was used and carbon-free alloying elements were added. For this reason the alloys are all low in carbon. The results of these tests are given in Table I.

From these data it is evident that when carbon is low,

copper at least up to about 5 per cent does not make iron harder and it does not impair the cold-working properties of iron. Manganese makes iron harder and more difficult to work and when about 2 per cent is reached the resulting alloy is too brittle and hard for ordinary commercial uses. In the same way chromium above about 2 per cent makes the alloy hard and tough and difficult to work, although not brittle.

SUMMARY

We may summarize the findings as follows:

1. Copper added to iron produces red-shortness over a certain temperature range. The degree of brittleness and the temperature over which it occurs increase with an increase of copper content. It is believed that this brittleness is due to an intergranular film of copper or an alloy or compound of copper.

2. The red-shortness due to copper is removed by the addition of manganese or chromium, but the amount necessary depends on the copper content. This observation explains why copper added to iron causes red-shortness, while it does not cause red-shortness in steel unless added in excessive amounts.

3. The addition of copper up to at least 3.50 per cent apparently does not impair the cold-working properties of the alloys. Beyond 2 per cent of manganese the alloys become too brittle to work, while with more than 2 per cent chromium the alloys become hard and tough.

Reconstruction of Sugar Refineries in France

The refining of sugar in northeastern France was particularly affected by the war. Nearly all the French sugar refineries were located in the Departments of Aisne, Ardennes, Marne, Nord, Oise and Pas-de-Calais, and in these regions sugar beets were raised in enormous quantities. Of 217 refineries in France, 170 were established in these departments, and 145, valued at \$50,000,000 prior to the war, were destroyed.

The annual pre-war production, which averaged approximately 750,000 tons, fell to 180,000 tons. The present production amounts to about 300,000 tons. Immediately after the war refiners showed some hesitancy in regard to rebuilding their establishments, but Consul Paul H. Cram at Nancy reports that work is going on rapidly at present, and it is expected that practically all the refineries will be in operation in 1925. Of the 47 destroyed in the Department of the Aisne, 22 will resume operation in the course of the present year.

Problems in the Preparation of Copra and Coconut Oil

BY HARVEY C. BRILL

IN A RECENT number of *CHEMICAL & METALLURGICAL ENGINEERING* (1920, vol. 23, p. 37) Dr. Alvin J. Cox, director of the Bureau of Science, Manila, 1912-19, discussed the various products of the Philippine Islands which assume some importance as commercial commodities to the United States. Among these he gives coconuts and copra a very high rank. According to figures compiled by Dr. Cox (*Bureau of Science Press Bulletin*, 1916, No. 54) the annual crop produced in the islands in 1916 amounted to nearly 500,000,000 nuts. The copra exports were 72,277 long tons and the coconut oil exports 16,091 long tons for 1916.

Since this time the exportation of oil has increased and the copra shipments have fallen off. In other words, more copra is being converted into oil in the islands and this oil is then shipped.

THE DRYING OF COPRA—NATIVE METHOD

For the production of oil from coconuts several operations are necessary: The native methods are—where possible—to husk the nuts, divide them into halves and place them in the sun until the meat dries sufficiently to break loose from the shell. They are then removed from the shell and allowed to dry for a further period of time in the sun. When sufficiently dried to be acceptable to the buyer the copra is bagged and sold. The preceding method obviously can be operated only when sufficiently sunny weather prevails to bring about drying, and when one learns that the tropical regions quite often have a marked rainy season he understands that this method would not be successful for year-around operation. It has other handicaps, but the one just enumerated is sufficiently great to make a better method desirable. The second method used by the Filipino is to dry the halved nuts on a grill or tapahan. A trench is dug and over this a furnace is built, which is covered with a bamboo grill. The halved nuts are piled on this grill and a fire of shells and husks is made in the furnace for the purpose of drying the meat. Shells and husks make a poor fire and as a consequence the meat is badly smoked and poorly dried. If an honest attempt is made to dry the meat much of it is scorched and smoked before the exterior of the pile has dried at all.

It is apparent that not enough can be done in the improvement of the methods described to warrant their continued use.

USE OF SULPHUR DIOXIDE IN DRYING PROCESS

The Bureau of Science carried out a series of experiments in which the meat was first treated with sulphur dioxide much as dried fruit is treated in California. The results were promising. A twelve-hour treatment with sulphur dioxide was found to give favorable results. The meat lost 37 per cent of its total water content during the treatment and at the end of ten days, during which it was placed in a shed most of the time due to the almost continuous rainfall, it had lost 73 per cent of its total water content. Two effects were produced by sulphuring: (1) The cell walls of the meat were softened and the copra dried more readily afterward; (2) the presence of small amounts of sulphur dioxide prevented the growth of micro-organisms. The disadvantages of the method are the cost of the small sheds

in which the treatment might be given and the length of time needed for drying the copra after sulphuring. However, the oil obtained from such copra is almost water white and will need little refining. The cost of refining oil is estimated at \$4 per each 1 per cent fatty acids per ton of oil, so that oil free from fatty acids is very desirable.

Attempts have been made to introduce artificial driers, making use of hot air. These attempts have met with very little success thus far for two reasons: The machine is expensive in cost and in operation, and a prejudice exists against artificial drying. The belief prevails that a loss of oil results as a consequence of artificial drying. Experiments carried out by the Bureau of Science would tend to disprove this belief.¹ However, Dr. Sherman of the Visayan Oil Co. at Cebu contends that oil collects in its driers in the air outlets. A good opportunity for investigation exists here. What is the best temperature for drying? Is a vacuum advantageous? (Recent developments in drying vegetables prove that vacuum drying is preferable.) And of course the type of drying machine should be considered—one that will minimize handling of copra would be best.

EFFECT OF FUNGUS GROWTH

Investigation has shown that the molding of copra will proceed as long as the moisture content is 10 per cent or more. Much of the copra of the Island of Luzon will run as high as 20 per cent moisture content. Such copra when put in a storehouse becomes hot after a short period of storage, and large quantities of carbon dioxide are given off due to the metabolic processes of the fungi. This carbon dioxide reaches a maximum after an interval of three or four days' storage, the temperature recedes and the quantity of carbon dioxide given off decreases. Molding apparently ceases. Has the high temperature been caused by the activity of the fungi? And have they been destroyed by this high temperature? Copra which has undergone such an experience comes out a black, moldy mass with an acid number as high as 25 in many cases calculated as oleic acid. Such oil cannot be refined to an edible oil except at great expense and high loss in oil. Such an experience should not be permitted to occur. Besides the causing of acidity and rancidity of the oil, the molds destroy much of the oil when they grow. Investigations conducted by the Bureau of Science showed that this varied from 20 to 50 per cent of the total oil present.

EXPRESSION OF THE OIL FROM THE MEAT

To obtain the oil from copra, the copra is first ground and the heated meat sent through expellers. The most advantageous temperature for this operation is not known in the Philippine Islands. Such data should be determined. The influence of the moisture content on the operation has not been thoroughly investigated and deserves such investigation—i.e., is a residual quantity of moisture helpful in obtaining a high percentage of the oil by expression? Some mills leave a residual oil content as low as 8 per cent after the expeller treatment, others insist that this is not economical because of the wear and hardship on the machinery, and the latter prefer to leave in an oil content of 12 to 15 per cent. They then steam this copra meal and subject it to hydraulic pressure. Here a good solvent would be an efficient helper. A solvent for use in the tropics

must not have too low a boiling point, because of the high temperature of the condensing water.

The copra meal remaining cannot be used as a fertilizer because of its oil content; it cannot be disposed of as a cattle feed, since cattle raising does not flourish in the islands; and for the last five or six years it could not be shipped elsewhere for cattle feed because of the prohibitive freight rates. This emphasizes the need for a solvent and the installation of an extracting process which would leave a cake which because of the absence of any oil would be available for fertilizer purposes.

OTHER METHODS SUGGESTED TO SEPARATE THE OIL

It seems that the process of converting coconut meat into copra might be avoided by making use of some method that would take the oil from the fresh meat. Indeed, O. Vyner of British North Borneo reports a recently patented method which does this. When the Bureau of Science attempted to repeat his experiments the experimenters were unable to duplicate his results.

The Filipinos do this on a small scale by pulping the meat, allowing it to ferment for several days, which brings about a disintegration of the cellular matter by the bacteria, warming over a direct fire and then separating the liquid portion from the solid material by means of crude presses. Their yield of first-class oil is small, but the product commands a higher price than the average coconut oil that is on the market.

In the attempt to separate the oil from the fresh meat a number of difficulties are met. The freshly grated coconut meat does not give up its oil readily by pressing. By treating the meat with water and live steam for three hours before pressing, 80 per cent of the oil can be removed by one pressing. Further steaming and pressing would remove a large part of the residual portion. The liquid obtained by pressing is a white emulsion, consisting of cellular tissue, oil and water. How to remove the oil from this is a complicated problem. A De Laval cream separator works fairly well until the bowl becomes packed with the cellular matter. A specially constructed centrifuge, possibly modeled after the wringer used to dry explosives, might be used.

When this liquid was cooled to a temperature of 15 deg. C. and allowed to stand twenty-four hours, then gently warmed to room temperature or slightly above, the oil could be readily separated.

Treatment of the ground meat with hot solutions of acids, bases and various salts either at atmospheric pressure or in an autoclave did not facilitate the separation, but resulted in deterioration by hydrolysis.

The establishment of the drying and pressing method would mean that the nuts would be assembled and the oil manufactured from them at some central point. This would likely be as advantageous for the islands as a whole as the establishment of sugar centrals and the abolishment of the crude, wasteful, native sugar mill has proved to be. It would mean one other thing: that the press cake would be sweet and wholesome and fit for human food and not a nuisance as it now is.²

The solution of these problems pointed out and the preparation of pure coconut oil without subsequent refining need two things—men experienced in plant operation and acquainted with chemistry, and men with capital and a willingness to spend some of this in experimental work.

Determination of Melting Points

General Disagreement in Melting Point Values as Given in Handbooks—Suggestions on Methods to Be Used in Determining the True Values—The Melting Point of Potassium Chlorate by a New Method

By CLIFFORD D. CARPENTER

WHEN one wishes to know the melting point of a substance it is most convenient to refer to some handbook containing a table giving a list of substances and their important physical constants. In the case of the important organic substances the melting points are rather definitely stated and not much doubt is indicated, although in a few cases two values are given differing by one or two degrees, but they are oftener given in the tenths. It is quite a different case when one desires to know the melting point of an inorganic compound. If it is listed, a single value may be given, but many are indicated by two results differing from ten to thirty degrees or more. If the value desired to be known has only one value given, it might readily be assumed that it was very definitely known, but if one is unfortunate enough to look into two handbooks, he will likely end in doubt, as it often happens that such tables do not agree. Take, for example, the melting point of potassium chlorate. The values given in three typical handbooks on physical constants are 334 deg.,¹ 357 deg.,² and 370 deg.³

There are two main reasons why the data for the organic compounds are so much more satisfactory than those for the inorganic. Most of them melt at relatively low temperatures where the mercury glass thermometer is satisfactory, when properly standardized, to measure such temperatures. Then, too, the purity of an organic compound is ordinarily defined by its physical constants, usually its melting and boiling point, making a knowledge of such facts especially valuable.

In the case of the inorganic compounds, most of them are beyond the range of a mercury glass thermometer, or at least in the upper part of such range, where considerable difficulty arises in defining the absolute temperature. Then, too, it is not so difficult to determine the purity of inorganic substances, as there are well known analytical methods. When a search of the literature is made it is found that very few of the melting points of inorganic substances have recently been determined. Since the development of accurate temperature-measuring instruments, platinum resistance thermometers, thermocouples, etc., and a careful study of well-defined points for their calibration have taken place only in the last few years, it would seem that much of the present lack and inaccuracy in data for the melting points of inorganic substances is due to the fact that no careful attempt has recently been made to redetermine them. The main considerations in melting point determinations are: The method used in bringing the compound to the desired temperature, the kind and accuracy of instrument used in measuring the temperature, the physical evidence used in recognizing the point at which the compound melts, and the purity

of the compound. The first two involve the question of apparatus. The last two depend upon the nature of the compound under consideration.

APPARATUS

A practical apparatus for the determination of many melting points and its arrangement is illustrated in Fig. 1. It includes a stirrer, well-lagged beaker and a platinum resistance thermometer with its Wheatstone bridge, galvanometer and reading scale. The special feature of the stirrer is its adjustability with regard to speed, having three different size pulleys, both on the motor shaft and stirring rod. The stirring rod can be raised and lowered to accommodate the height of the beaker. While the one illustrated is an iron rod with a

FIG. 1. MELTING POINT APPARATUS

loop in the end of it, a glass rod may be substituted when desirable. The stirring apparatus is an entirely independent unit and can be moved without disturbing any of the other apparatus.

Another convenience is the clamp which carries the platinum resistance thermometer, which prevents the loosening or breaking of the leads at the head of the thermometer. The beaker is lagged by wrapping with moist asbestos paper until about $\frac{1}{2}$ in. thick. Two small holes are cut in the asbestos, one opposite the other, for windows. A light is placed in front of the one on the opposite side and the experimenter can then observe the behavior of the compound when the tube or bulb that contains it is lowered in the bath until it is in front of the window.

The bath is a mixture of potassium and sodium nitrate with a melting point close to 220 deg.⁴ As the

¹Chemiker Kalender.

²Van Nostrand, Chemical Annual.

³Kaye and Laby.

⁴Cawth, *J. Phys. Chem.*, vol. 2, p. 207; Scudder, *J. Am. Chem. Soc.*, vol. 25, p. 161; Smith and Menzies, *J. Am. Chem. Soc.*, vol. 32, p. 899.

molten nitrate is colorless and transparent, it offers no obstruction to observing the changes in the compound. The temperature of the bath can be kept within very narrow ranges, ± 0.2 deg. or less, even at 400 or 500 deg. C. The heat capacity of the molten liquid is great enough that its rate of cooling or heating is slow so that the platinum resistance thermometer registers the slightest change in temperature. With vigorous stirring the bath keeps a uniform temperature. The platinum resistance thermometer and its accessories are assembled as directed by the Bureau of Standards.⁵

NATURE OF THE COMPOUND

Some typical cases are discussed below. In the first three, the disappearance and reappearance of solid are the physical evidence. In the fourth case the "rest" in a cooling curve is taken as the point. The fifth case is the typical freezing point curve of a two-component system. In the first four cases it is assumed that the pure substance can be easily obtained.

CASE I

Stable above its melting point, inert toward glass or quartz. The apparatus above described is used. If temperatures much above 600 deg. C. are to be employed, a transparent quartz beaker as bath and a similar tube containing the compound must be used. The compound is introduced into a long closed tube and lowered into the bath until it is in front of the window. The bath is heated and the temperature is recorded when the solid disappears. The bath is then allowed to cool down slowly and when the solid reappears the temperature is again noted.

Should there be much difference between the temperatures of disappearance and reappearance of solid phase, the undercooling may be prevented by dropping a small crystal into the melt when the temperature is lowered a fraction of a degree below the temperature at which the solid disappears. In practice it has been found that the heating and cooling of the bath by alternately increasing and decreasing the heat may be so controlled that its temperature will change only a small fraction of a degree over any period of time. This makes it possible to keep the disappearance and reappearance of the solid within a very small temperature range. After several operations as described above, the true melting point is obtained as an average of the observations.

CASE II

Undergoing very slow decomposition, or acts very slowly upon quartz or glass. The compound is introduced into a tube as described in Case I and its approximate melting point determined. After the approximate melting point is known, the bath is set near that temperature and a new sample of the compound in a new tube is introduced and the temperature slowly raised until nearly all the solid melts and then cooled, until the crystals reappear. The temperature of appearance of new crystals and the time which the tube containing the compound is put into the bath and of appearance of new crystals are noted and recorded. The bath is alternately heated and cooled and the temperature and time of each appearance of new crystals are noted and recorded. The lowering of the temperature on each successive reading, as a result of the increase in amount of decomposition products or of reaction between the containing tube and the compound,

is a function of the time, and the effect may be indicated as a time temperature line. By a very small extrapolation of the line the true melting point of the pure compound is determined.

CASE III

Volatile below or undergoing rapid decomposition at its melting point. The pure compound must be sealed in a heavy walled tube. The quantity of solid introduced should nearly fill the tube. It may then be tied to a glass or quartz rod by a thin iron wire and lowered into the bath until in front of the window. In such cases the tripod supporting the bath should stand in a large iron pan, and should be well surrounded by a jacket with observation windows to prevent serious accidents in case the decomposition pressures should burst the tube. The platinum resistance thermometer should also be protected by a partition between it and the tube containing the compound.

CASE IV

Acts vigorously on transparent tubes, glass and quartz, but is inert toward metals or carbon. This case is a typical cooling curve problem. The use of this

FIG. 2. EXTRAPOLATION LINE SHOWING RATE OF DEPRESSION OF MELTING POINT OF POTASSIUM CHLORATE DURING PYROLYSIS

method is typically illustrated in recording the melting point of a metal in a graphite crucible as employed in calibrating the resistance thermometer.⁶

CASE V

Melting points of hydrates; or a substance difficult to obtain pure but readily estimated when mixed with a second component. The melting points of the pure substances, the addition products (hydrates, etc.) can be estimated by extrapolation of the "freezing point" curves of such two component systems.

THE MELTING POINT OF POTASSIUM CHLORATE

In the determination of the melting point of potassium chlorate, the apparatus described above was used. The temperatures were determined by the aid of a platinum resistance thermometer calibrated against the three points, ice water, water steam, and sulphur-sulphur vapor, as described by the Bureau of Standards.⁷

The method employed was the one described in Case II. Pure potassium chlorate was obtained by repeated recrystallization of a c.p. Merck sample.

Pure potassium chlorate decomposes very slowly at its melting point. If then it is melted and slowly cooled, the reappearance of crystals will take place at a temperature slightly below its melting point. If the temperature is again raised and lowered, the second reappearance of crystals will be at a still lower temperature. If the raising and lowering of the temperature

⁵Reprint 121.

⁶Loc. cit.

⁷Reprint 124, loc. cit.; J. Am. Chem. Soc., vol. 41, p. 748 (1919).

are kept within narrow limits, this lowering will be a function of the time. During the course of this experiment the temperature was kept within ± 2 deg. of a mean. The crystals were never allowed to disappear completely as the temperature was raised, thus preventing undercooling as the temperature is lowered. The bath was slowly cooled and the appearance of new crystals was especially striking and was accepted as the point at which the temperature was to be noted. The data and its interpretation are given below.

The temperature is recorded in terms of ohms. The record of the readings are given:

	Time.	Ohms.
Introduction of tube.....	2:30	116.35
First appearance of new crystals.....	2:54	116.32
Second appearance of new crystals.....	3:06	116.30
Third appearance of new crystals.....	3:12	116.25
Fourth appearance of new crystals.....	3:26	116.23
Fifth appearance of new crystals.....	3:34	116.20
Sixth appearance of new crystals.....	3:45	

It is seen that the extrapolation of the line running through the points taken intersects the ordinate at zero time at 116.425 ohms. The temperature corresponding to 116.425 ohms resistance is 357.10 deg. C.

CONCLUSIONS

A brief résumé of methods used and some proposed improvements in determining melting points have been given. The melting point of potassium chlorate has been redetermined by a new method.

BY WELLINGTON GUSTIN

Corporation Casting Metal Furnished by Contractor Held "Manufacturer"

Who is a manufacturer under the internal revenue act was decided by the Federal District Court in the recent case of Dayton Brass Castings Co. vs. Gilligan. The plaintiff corporation was formed for the purpose of manufacturing and selling brass, bronze, aluminum, white metal and all other kinds of metal castings. The Recording & Computing Co. had a contract with the Canadian Car & Foundry Co. for delivery of a large number of time fuses for shrapnel shells for the Russian Government. Each fuse, when assembled and completed, consisted of forty-five parts. The Dayton company entered into contracts with the Recording company to make for use in fuses, from ingots and patterns to be supplied by such company, certain rough castings, to be paid for by the pound and to be delivered at such company's plant.

The work done by the Dayton company concerned but four of the forty-five parts entering into a completed fuse. None of such four parts was at the time of their delivery fitted for insertion into fuses, but the Recording company was required to further prepare them before they were perfected for use. Therefore the Dayton company contended it was not subject to the war munitions tax imposed by Congress and approved Sept. 8, 1916. For failure to make a return within the statutory time the company was directed to pay as a tax the sum of \$18,860.83 and a penalty of

50 per cent additional (\$9,430.42). This was paid under protest and a claim was preferred for a refund of the tax and penalty, on the ground that it was not subject to such tax. The Commissioner of Internal Revenue ordered a repayment of the penalty, but otherwise rejected the claim. The company began suit to recover, on the grounds that the articles cast and delivered by it were parts of fuses, that in the performance of the work it was not engaged in manufacturing and was not a manufacturer, and that in delivering the castings in the manner provided in the contract it did not sell or dispose of them within the terms of the act.

However, the court held the company was a manufacturer, under the act, and that it was not necessary that a manufacturer produce a finished product. It said castings made for use in shell fuses, though still in their rough condition and requiring numerous processes to prepare them for such use, cannot be used without further treatment for any purpose other than that for which they were designed and are relatively complete parts. It further said that a corporation casting metal and delivering it to the owner "disposes of" such castings.

Again the provision of the act, for determining the munitions tax in case of articles sold below the fair market price to evade the payment of the tax, does not prevent the imposition of the tax on a manufacturer of castings for shell fuses from metal furnished him by the maker of the fuses.

The corporation which received from a munition maker metal owned by such maker, and made therefrom castings for shell fuses, which it returned to such maker, had a lien on the metal for its labor thereon and its profits, which made it a special owner of the metal, taxable under the act imposing a tax on war munitions.

Sale Contract Held Subject to Rule Fixing Percentage of Estimated Output

In the action by the N. P. Sloan Co. against the Standard Chemical & Oil Co. the U. S. Circuit Court of Appeals affirmed judgment in favor of the plaintiff. The action was on a contract for the sale of the season's output of the seller, estimated at a stated quantity. Both parties were members of a voluntary association called the Interstate Cottonseed Crushers' Association, and the court said such contract was subject to the rule of the association that the seller is required to deliver at least 85 per cent of the estimate, where the contract did not contain an express exception from that rule as required by another rule of the association permitting specific written contracts at stated special conditions.

The contract estimate called for 2,000 bales of linters at 3c. per lb. The Standard Chemical & Oil Co. delivered only 1,324 bales and claimed full compliance with its obligations because it delivered its entire season's production. On the other hand, the Sloan company claimed it was entitled to 1,700 bales, or 85 per cent of the contract estimate. It went upon the market and bought 376 bales of linters, representing the difference in controversy, and paid 8½c. per lb., thereby losing 5½c. per lb. on the contract price. The net loss to plaintiff, Sloan company, at 5½c. per lb. was \$7,312.16 and judgment was rendered for this amount. Further, it was contended by the Standard Chemical & Oil Co. that there had been a settlement of the difference in controversy by an accord and satisfaction. But

such company's own testimony that the Sloan company agreed to accept a specified shipment of 213 bales of linters in full satisfaction of its demands also showed the goods in that shipment were rejected by the Sloan company, with the other's acquiescence, because of their condition.

The arbitration was had in accordance with the rules of the association. The Standard Chemical & Oil Co. did not sign the letter of submission, but received it, and had due notice of the arbitration. The committee's award was that to fulfill the contract a minimum quantity of 1,700 bales of linters, of an average of 475 lb. per bale, at 3c. per lb. was necessary. This award was the same as the judgment rendered after trial.

Defendant contended that the agreement to arbitrate was revoked. The court said it was true that defendant failed to sign the submission and declined to authorize the purchase of linters on its account, but that would not constitute a revocation. Revocation comes about by act of the parties or by operation of law. Now there was no claim of such by operation of law, and before there could have been such by act of the parties there would have to be notice to the arbitrators. Failure to sign the submission was not sufficient.

Again, the court said, an award fixing the number of pounds which should have been delivered according to the average weight of the bales was not beyond the submission of the question whether the seller should deliver a stated number of bales to the buyer. Instead of speaking in terms of bales of linters, it deals in pounds, and fixed the average weight per bale.

Non-Riparian Owner Has No Right of Action for Pollution of Stream

In a memorandum decision the Court of Errors and Appeals of New Jersey affirmed judgment rendered against the Egyptian Lacquer Manufacturing Co. in its suit brought against the Chemical Co. of America. The plaintiff has a factory in Rahway, N. J., for the manufacture of chemical products requiring a large quantity of water which was supplied to it by the city. In its suit it set out that the Chemical Co. of America had a factory located at or near the Rahway River and emptied therein refuse from its factory above the intake of the city, which so polluted the water furnished by the city that the Lacquer company was injured in its use and the conduct of its business was thereby prevented, to its great injury, and that the defendant knew that the water from the stream was being used by the city to supply its inhabitants.

It was not alleged that either of the parties, or the city, was a riparian owner other than that the Chemical company carried on its business "at or near" the Rahway River. But, said the court, assuming that both defendant and the city are riparian owners, it is clear that the plaintiff, Lacquer company, is not and that there was no contractual relation existing between the Egyptian Lacquer Co. and the Chemical company or between the defendant Chemical company and the city, as to the supply of water. Therefore the question presented in this suit was whether the Lacquer company had the right to maintain an action against the defendant, since plaintiff was not a riparian owner.

The court said: "We may assume in this case that a liability existed in favor of the city as a lower riparian owner for the pollution of the stream by a higher riparian owner; but there the obligation ceased,

for the right of action would not pass to a non-riparian owner merely because the latter had contracted with the city for the furnishing of the water, for his right depends upon his contract with the city, which might provide for the very character of water which was supplied. The liability of the defendant, if any, rests upon his violation of the legal right of a lower riparian owner, unless it had contracted with the plaintiff."

It was not contended that there was any contract between the parties. Neither was this a case of an indictment for creating or maintaining a public nuisance, or for the violation of any law against the pollution of a running stream, but a suit for damages resulting from a special injury based upon the non-performance of a duty which the Lacquer company claimed was due to it from the Chemical company. But the court found that the claims did not present or show the violation of a riparian duty to the injury of another riparian owner; neither did they show any contract between the defendant and the city, even if such a contract could inure to the benefit of plaintiff (which the court was of opinion it could not). Neither was it claimed there was a contract between the plaintiff and the city, nor that defendant, as a riparian owner, owed any general duty to the public, or a special one to the plaintiff.

Right of Stockholder to Inspect Records of Chemical Company

Seeking to inspect the books of the corporation, C. S. Goddard instituted mandamus proceedings against the General Reduction & Chemical Co. of Salt Lake City, Utah. It was alleged that Goddard wished to examine the books and records of the corporation in order to secure a list of its stockholders for the purpose of selling them stock in the Congressional Oil Co.

The Chemical company further alleged that it was engaged in the business of equipping and operating its plant for the general chemical reduction of ore at Salt Lake City and the manufacture of paint, and to raise funds for such purpose had sold a large amount of its own treasury stock on contracts and part payments; and that plaintiff was sending through the mails representations to such stockholders to induce them to break their contracts with such Chemical company and to buy stock from the plaintiff, to his gain.

Because of such use to be made of the list of stockholders, as alleged, the corporation contended such to be unlawful and the plaintiff not entitled to be permitted to have access to its stock ledger. Further, it was set up by the corporation, plaintiff desired the inspection to make a list of stockholders to whom he could send through the mails misleading and fraudulent advertisements, as he had done on a former list. But this charge, not supported by proof, was held to be insufficient as an excuse for refusing access to the books of the corporation to a stockholder.

Again the Chemical company alleged that the plaintiff was a cut-rate stockbroker and that his purpose in seeking the inspection of the books was to procure a list of its stockholders for threatened blackmailing purposes and for the unlawful sale to the stockholders of stock in another corporation, and to enable him to induce the stockholders to breach their contracts to pay for its stock. This, the court said, states no defense, since the acts alleged were not illegal, and the charge that they were for blackmailing was a mere conclusion.

Recent Work on Chromium:Tungsten Steel

— Methods of Magnetic Analysis

First of a Series of Articles Reviewing the Literature on Chromium:Tungsten Steels, Especially the Work of Japanese Investigators—This Article Contains a Description of the Methods of Magnetic Analysis Extensively Utilized

BECAUSE of the importance of chromium and tungsten in the manufacture of high-speed tool steels any publications of assistance to a rational understanding of the effects of these elements, alone and in combination, are of considerable interest and importance, especially as our knowledge of the constitution of these alloys is incomplete and metallurgists still disagree in interpretation of observed phenomena.

A series of such papers by Honda and other Japanese investigators has appeared, beginning about 1911, which is of added interest because of the pioneer methods of investigation which have been used. A list of the more important ones is appended. They are not readily accessible to English readers, in some cases German translations alone being available; so that a somewhat extended summary appears justified and will be attempted in succeeding issues of *CHEMICAL & METALLURGICAL ENGINEERING*. Magnetic methods of analysis, together with microscopic examination, have been largely depended upon, though other forms of testing, such as thermal analysis and expansion measurements, have also been used and correlated with the magnetic properties. In the present review, a brief description of the apparatus adaptable for metallurgical study will be presented.

EXPERIMENTAL METHODS USED

Four types of magnetic apparatus have been used in analysis of metals and alloys at normal and elevated temperatures. They are:

- (1) Beam balance.
- (2) Torsion balance.
- (3) Magnetometer.
- (4) Ballistic galvanometer.

Methods (1) and (2) both depend upon the measurement of the force exerted on a specimen placed in a

non-uniform magnetic field. They are the most sensitive and are particularly applicable where feeble magnetization is obtained. The magnetometer utilizes the deflection of a freely swinging magnetic needle caused by a magnetized specimen and has probably the widest range of sensitivity. The apparatus for the ballistic method consists primarily of a test coil surrounding the specimen and connected to a ballistic galvanometer. Neither of these two latter methods will be here described, as the principles involved in their use are well known and widely used.

THE BEAM BALANCE

The first of the four types of apparatus mentioned above is shown in Fig. 1, in which *ab* is an aluminum lifting arm suspended from a steel knife edge *c* and controls a pointer with a Wollaston wire 0.003 mm. in diameter, the position of which is sighted through a

FIG. 2. DETAILS OF SPRING AND OIL FLASK SHOWN IN FIG. 1

FIG. 1. BEAM BALANCE

microscope. The upper end of a steel spring *h* is attached to one end of the lifting arm, while the lower end of the spring is fastened to the bottom of a Dewar flask containing oil (to prevent rapid temperature changes). This oil flask can be moved up and down the weighing system very slowly while its total dislocation may be read on the torsion head *l*, as shown in Fig. 2, a twist of 1 deg. being equal to a flask movement of $\frac{1}{250}$ mm. The weighing system is also equipped with an oil stabilizer *i*. A small shell in which the weights are placed is shown at *f*, while suspended from the lower end of a magnesia tube *o* by platinum wires is a magnesia crucible *e*, in which the test-piece is held. Temperatures in the crucible are accurately determined by a rare-metal thermocouple, while the magnetic field in which it

¹On the Susceptibility of Iron, Steel, Nickel and Cobalt at Elevated Temperatures, K. Honda and H. Takagi, *Sci. Reports*, Tohoku University, vol. 1, p. 229.

is placed is drawn from the poles of a du Bois electro-magnet j ; k is an electric furnace, at the bottom of which is a narrow porcelain tube for the introduction of nitrogen in order to minimize oxidation of the sample. The position of the furnace may also readily be adjusted.

The field strength and its gradient may be measured by the induction method. In using the apparatus residual magnetism must first be removed by reversal of current before experimental readings are taken. The force exerted on the specimen may be weighed by this apparatus and is a measure of the magnetic susceptibility of the steel.

THE TORSION BALANCE

The torsion balance² used by Honda in his early experiments is shown in Fig. 3, and is substantially as follows:

A is an aluminum tube (with a movable counter-weight E) hung horizontally from a silver wire F 0.17 mm. thick, fastened to a torsion head G calibrated in degrees and which can be slowly adjusted by a screw. The free wire length can be measured up to its maximum by reference to the fixed peg K . At one end and at right angles to the tube A there is attached another similar tube B which is likewise attached to a magnesia tube C carrying a small crucible D suspended by platinum wires. To the other end of

FIG. 3. TORSION BALANCE

the tube A is fastened a vertical pointer moving before an adjustable scale. A damping apparatus H hangs freely under the tube A in a flask containing benzene and glycerine, by which arrangement the movement of the arm A becomes almost aperiodic. The entire apparatus is inclosed in a

zinc box ZZ . The specimen to be tested is placed in crucible D and its temperature obtained at any time by a platinum thermocouple which passes through the magnesia and aluminum tubes without disturbing the freedom of motion of the arm A .

A scheme for making field measurements² is shown in Fig. 4. A test coil S is hung vertically by a cord which is guided by the holder H and passes over two pulleys P_2 and P_1 to Q , which is used to pull up the coil. The stand R can quickly be moved through a short distance by L_1 and L_2 to measure the

field gradient. The apparatus is placed between the poles of an electro-magnet, S being vertical to the lines of force, while a ballistic galvanometer is used to meas-

ure induction. The settings are so made that at the upper end of H the test coil S is altogether out of the magnetic field. As was the case with the beam balance, magnetic susceptibility of the steel is measured, the intensity of magnetization of the specimen being proportional to the angle of rotation of the arm A in Fig. 3.

Both beam and torsion balance have a distinct advantage over the other magnetic methods of analysis mentioned in that they are applicable to alloys which are worked with difficulty or not at all, as they do not require specially finished test-bars.

Modifications of the equipment as described have been made from time to time in the various researches carried out by these Japanese investigators, but will not here be described, as a bibliography listing the various publications is given below. In these papers may be found details of various modifications used as well as more elaborate descriptions of the apparatus and methods employed.

Increased Costs in English Pottery Industry

Consul W. F. Doty, of Stoke-on-Trent, reports that manufacturing costs in that center of the English pottery industry have increased enormously over pre-war figures. Labor is 150 to 180 per cent higher than in 1913, fuel 200 to 255 per cent higher, clay 160 to 250 per cent, cobalt 230 to 566 per cent, flint, glaze, etc., 180 to 330 per cent, crates and straw 230 to 425 per cent, cartage 300 to 400 per cent, sagger marl and firebrick 275 to 290 per cent, and plaster 200 per cent higher according to data supplied to the Consul by the Staffordshire Pottery Manufacturers' Association.

Factors Influencing the Viscosity of Glue

BY F. J. CRUPI

AS is well known, the viscosity of glue solutions generally varies with their comparative water content. A glue solution with a high water content produces high dispersion of the molecules, and a consequent low viscosity; whereas a solution of the same glue with a less water content produces less dispersion and a comparatively higher viscosity.

GRADES OF GLUE AND COLLOIDAL PROPERTIES

There are many different grades of glue on the market, and it is noticed that a high-grade glue "B" shows a higher viscosity than an inferior grade "C"—each solution containing glue and water in exactly the same proportion. The cause of this may be explained as follows:

The former glue "B" may consist of colloids which are much larger than the colloids of glue "C"—that is, the colloids of glue "B" may consist of more molecules than the colloids of glue "C"; if so, this would decrease the dispersion of the molecules of glue "B" as compared with the molecules of glue "C." When discharged through a pipette, the more molecules there are in a given volume the more force they will exert on the sides of the vessel and the more resistance they will offer to deformation and flow. The colloids of glue "B," having a greater mass and concentration than "C," will obviously offer more resistance to flow. The glue solution "C," consisting of minor colloids and greater dispersion of the molecules, will flow more readily, since it offers less resistance to deformation—the molecules, having more freedom, will produce more flexibility, thus passing through the opening more readily.

A better conception may be formed when we compare this statement as an analogy with the flow of sand grain instead of glue. If we use a special pipette with a definite opening, and fill it with fine powdered sand, it will be found to flow much sooner than a coarser grade. Let's imagine the grains of sand as the colloids and the analogy is complete. But it does not always follow that the relative size of the colloids determines the viscosity. A glue solution may have colloids containing, for example, ten molecules, and another solution containing colloids made up of half as many (five) molecules and still be of the same size. Since the colloids of both glues are of the same size, we would expect to obtain the same viscosity, but it does not always follow, for the former colloids, containing more molecules, will produce more concentration and will offer more resistance to deformation, etc.; whereas the colloids containing five molecules—the molecules being greatly dispersed—will be more flexible and, therefore, would deform easier and flow more readily. In each of these mentioned factors the mutual attraction between the molecules plays an important part also.

The dispersion and size of molecules and colloids in glue are also influenced by various chemicals.

Some chemicals tend to increase the dispersion, and thereby lower the viscosity; while other chemicals act *vice versa*. Still other chemicals will coagulate a glue solution to a more or less extent, which is really the combining of molecules into large colloidal masses. When certain acids are added to a glue solution, they will produce an increase in dispersion and lower the

viscosity. Formaldehyde and others produce a decrease in dispersion and a higher viscosity.

It is obvious how temperature would affect viscosity, since an increase in temperature will increase the distance between the molecules, causing a lower viscosity, while a decrease in temperature is *vice versa*.

Unless pipettes used are identical in bulk, size, shape and in almost every possible way, it will be found difficult to obtain accurate comparative results. The fact that a pipette will discharge water in a given time does not follow that a different pipette—different size, shape, etc.—which also discharges its contents in that given time will give comparative results with glue. A pipette which is twice as large in bulk as another can be adjusted with an aperture which will discharge its contents in the same time, in the former pipette the aperture being twice as large as the latter. The various effects of these differences can be imagined when we review the colloids, etc.

A stop watch is used and its figures adopted as a means of classification. The length of time a solution of glue remains exposed in the hot water bath, before being actually tested, is found to affect the viscosity, as the water gradually evaporates.

RELATION OF VISCOSITY TO JELLY STRENGTH

Generally the jelly strength of a glue varies with its viscosity. When a finger or rod displaces the colloidal particles of a cold jelly of glue, they act like small solid rubber balls, the hardest rubber balls offering the most resistance to pressure. So in a glue jelly, its strength depends on the concentration of the molecules or the quantity of molecules which make up the colloids. Thus a glue containing colloids made up of ten molecules would offer more resistance than a glue whose colloids are of the same size and consist of only five molecules. The factor of dispersion also affects jelly strength. There are instances where, although the viscosity is lower than a certain standard, the jelly strength is higher. This may be due to the fact that although the molecules which constitute its colloids are less and more highly dispersed, the force of mutual attraction is greater.

Another reason may be that sometimes a glue may form big colloids with a large number of molecules, whereas another glue may form colloids half as big and containing half as many molecules. Of course, the big colloids would take longer to go through the pipette than the small colloids and thereby have a higher viscosity; but it is found that they have quite the same jelly strength, since the force of resistance would be the same in each arrangement of the molecules.

RELATION TO TENSILE STRENGTH, ETC.

Along these principles, then, it should also follow that the tensile strength of the dry glue should vary with the distance and mutual attraction between the molecules. It does not follow that a glue with a strong jelly should always have a strong tensile strength. The relative size of the colloids has very little influence on tensile strength. The characteristic properties of a glue depend on the strength and arrangement of the forces of attraction which hold the molecules together. Hard glues are glues in which the forces that exist between the molecules are very strong and hold them together so that they cannot easily be distorted. An elastic glue is one in which the same forces act to restore its original shape once it has been distorted.

Brooklyn, N. Y.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Rust-Preventing Mixture.—GEORGE S. MORGAN, of Toledo, Ohio, claims the use of the following mixture for preventing rusting and corrosion of metals: Litharge, 1 part; fatty acids, 2 parts; paraffine oil, 60 to 200 parts. (1,364,134; assigned to Edgar G. Behr, of Detroit, Mich.; Jan. 4, 1921.)

Sulphuric Acid.—If mechanical burners are employed in the chamber process for making sulphuric acid, the quantity of dust carried by the burner gases is large and this dust is not removed in the usual dry dust chambers. Consequently the acid in the Glover tower is made very dirty and when arsenical pyrites are used is highly arsenical. JAMES BROWN, of Manchester, England, modifies the system of dust removal by adding a wet scrubbing system after the usual dust collector. The gases pass first through a coke-filled tower in which H_2SO_4 of sp.gr. 1.5 to 1.7 is circulated, then through two coke filters in series followed by a blower and a small coke filter to remove drops of acid condensed by the fan. By means of heat-interchanger pipes passing through the dry dust chamber, the gases are reheated by the incoming raw gas. In this way it is possible to produce Glover tower acid of high strength which is waterwhite and is dearsenicated down to 5 to 10 parts per million even when using arsenical pyrites. From time to time the acid circulating in the first scrubber is settled in tanks and the clear liquor separated from the sludge. Specially designed distributors are required to prevent clogging. (1,365,964; Jan. 18, 1921.)

Continuous Calcination of Carbon for Electrodes.—High-grade carbon electrodes for certain processes require a carbon of high purity and one as nearly as possible free from contained volatile matter. The principal source of such pure coke is the well-known petroleum coke resulting from the distillation of petroleum. This coke as it comes from the oil stills contains from 6 to 12 per cent, of volatile matter, which must be driven off almost completely (to a small fraction of 1 per cent) before the coke is suitable for the manufacture of high-grade carbon electrodes. This volatile matter is driven off by heating the coke to temperatures in the neighborhood of 1,100 deg. C. and in a manner to prevent contact of the hot coke with the air or other gases which would cause oxidation. Several difficulties have been encountered in attempting to calcine coke by a continuous electrical process. Due to the negative temperature coefficient of resistance, there is a tendency for the current to follow the path first established. This results in overheating a portion of the charge and insufficiently heating the remainder. Furthermore, the raw coke is a poor conductor until the volatile matter has been driven out. WILLIAM HOOPES, of Pittsburgh, Pa., has devised a process which overcomes these difficulties. A furnace of the vertical shaft type is made from three flanged steel sections. The sections are insulated from one another and the upper and lower sections have connections for the heating circuit. These latter sections are lined with carbon so as to provide good electrical contact between the shell and the coke charge. The middle section is provided with an insulating refractory lining. The heated portions of the shell are jacketed for water-cooling. The coke charge is fed continuously through a hopper at the top of the furnace. A portion of the gases escaping during calcination is washed, cooled and circulated counter-currently through the furnace. Cool gas entering at the bottom of the furnace rises through the charge. In this way more even heating is obtained and the charge is conductive by the time it reaches the zone of electric heating. (1,366,457 and 1,366,458, assigned to Aluminum Co. of America; Jan. 25, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Addition to Program Rochester Meeting A.C.S.

The only addition made during the past week to the program for the Rochester meeting of the American Chemical Society was an address by Charles F. Chandler, professor emeritus of Columbia University. He will deliver the principal address at the general meeting the night of April 27.

A cablegram from Mme. Marie Curie to the effect that she regrets that she will not be able to re-arrange her plans so as to arrive in the United States in time to attend the American Chemical Society's meeting was received by Dr. Charles L. Parsons, secretary of the society.

Experimental Lecture on Radium

Interest in the forthcoming visit of Mme. Curie to the United States is reflected in the program of the New York Section of the American Electrochemical Society for April 8. Dr. R. B. Moore, chief chemist for the United States Bureau of Mines, will deliver the address of the evening at the Chemists' Club. Dr. Moore will make his address an experimental lecture on radium. He is well qualified to discuss this subject in an interesting manner, as he had charge for the Government of the plant in Denver which produced about 7 g. of radium salt for the National Radium Institute and the Bureau of Mines.

Recent Advances in Organic Chemistry

Prof. James F. Norris of the Massachusetts Institute of Technology addressed the Philadelphia Section of the American Chemical Society at its regular meeting on March 17, at the Engineers' Club. His subject was "Recent Advances in Organic Chemistry," and with the aid of lantern slides he gave an exceedingly interesting review of the progress in this branch of science during the past ten years.

Many reactions known heretofore only in textbooks have become of great industrial importance. For example, the conversion of ethylene to glycol and of pentane to amyl acetate involve reactions that have been known for years, but it is only recently that anyone thought seriously of operating them on a commercial scale. Propylene is now recovered from oil-cracking stills and is converted into isopropyl alcohol, which shows great promise as a substitute for the ethyl variety. The action of chlorine on acetylene produces dichlorethylene and tetrachlorethane, which are now finding application as solvents.

SYNTHESIS OF NATURAL PRODUCTS

The synthesis of natural products may be called the second chapter in the recent progress of organic chemistry. The structure of turmeric has been shown to be similar to that of acetylacetone. Fischer synthesized tannin from gallic acid and certain glucosides. The speaker paid a tribute to Willstätter for his work on chlorophyll and the coloring matters of flowers.

The rubber molecule is now believed to contain a ring of twenty carbon atoms, formed by the condensation of five isoprene chains. About twenty-five different syntheses of isoprene have been developed. Much of this work was done in Russia, as prior to the war Russia held the leadership in the field of paraffine compounds, just as Germany did in aromatics. Besides this extensive work on isoprene, Russian chemists have studied the polymerization of other hydrocarbons and have prepared many different substances with the physical properties of caoutchouc but differing from it chemically. The German synthesis of rubber during the war started with the hydrogenation of acetone, followed by dehydration to produce methyl-isoprene. After this material had been allowed to polymerize for about four months, a so-called "methyl-rubber" was obtained.

In the realm of sugar chemistry marked progress has been made. The preparation of ethers and esters of the various sugars has been especially valuable in studying the tautomerism and ultimately the constitution of these compounds. The speaker praised the recent excellent work of Hudson in this field.

FERMENTATION AND ENZYME REACTIONS

Fermentation processes and enzyme reactions have come into prominence during the past few years, especially on account of the production of acetone and butyl alcohol in this manner during the war. Fats can now be produced by the fermentation of carbohydrates, the reaction being controlled by the addition of sodium sulphite. Great progress may be expected in the near future through this control of enzyme reactions by the addition of inorganic salts.

CATALYSIS

In discussing the progress in synthetic methods, the importance of catalytic reactions was emphasized. Much has been learned regarding the specific properties of different catalysts. For example, nickel is especially valuable for hydrogenation, copper for dehydrogenation, and the oxides of aluminum or tungsten for dehydration. The development of catalytic promoters shows great promise. The enormous production of acetaldehyde, acetone, acetic acid and alcohol from acetylene was cited as one of the best examples of the commercial application of catalysis in organic chemistry. These processes were operated successfully in Canada during the war, and the yields and efficiencies were extraordinarily high for organic reactions. The production of many other compounds from acetylene is now being studied, such as pyridine, thiophene and acetic anhydride.

Regarding the question of valence, a great deal of evidence has been accumulated in favor of trivalent carbon and univalent and quadrivalent oxygen. Hexaphenyl-ethane and other compounds containing only carbon and hydrogen have been found to ionize and conduct electricity. It may be that the long sought "free radicals" will some day be produced. Electronic conceptions are destined to play an important part in future developments.

APPLICATION OF PHYSICAL CHEMISTRY

The greatest advance in the past ten years, in the opinion of Prof. Norris, has been the growth of the dynamic conception of the organic molecule. We used to think that the carbon and hydrogen atoms "stayed put" just the way we drew the lines in the structural formula, but the present tendency is to think of the molecule as a seething mass of moving atoms. The extensive work on tautomerism and desmotropy has been the chief cause of this dynamic conception. Equilibrium studies of the keto and enol forms in a wide variety of solvents have been especially valuable. Many organic reactions have recently been found to be reversible, thus making it easier to apply the laws of thermodynamics. In conclusion the speaker stated that he believes the application of physical chemistry to organic reactions offers the greatest opportunity for advancement at present and in the immediate future.

To Visit Mining Experiment Stations

Plans for the work at several of the mining experiment stations of the Bureau of Mines during the next fiscal year will be discussed at conferences which will be held at these stations between Director Bain and Dorsey A. Lyon, supervisor of stations, and the local staffs. Messrs. Bain and Lyon will leave Washington April 10 and will visit the stations at Bartlesville, Rolla, Mo., St. Louis, Minneapolis and Birmingham.

Ceramic Appropriation Fails in Ohio

The Ohio Legislature has failed to include in its appropriations the \$15,000 item proposed as the state's part of the co-operative support being given to the Bureau of Mines ceramic station at Columbus. The station soon will have been established four years, but the only appropriation which has been forthcoming is that allowed by the Federal Government.

The failure of Ohio to appropriate for this station probably will be called to the attention of the ceramic industries in that state in order that they may bring home to their legislators the benefits accruing to Ohio by reason of the location of the station within its borders.

Wage Changes at Holyoke Paper Mills

The American Writing Paper Co. after a conference with the leaders of the various local labor unions has announced a cut in wages averaging 15 per cent. The reduction is not horizontal, as recent wage advances in case of certain classes of labor had decreased the differential between skilled and unskilled labor farther than was considered necessary or desirable. This factor was considered in the new rates.

The independent mills of the district have for the most part declared their intention of reducing wages in general accord with the policy of the American Writing Paper Co.

The Crocker McElwain and Chemical Paper companies of Holyoke have reached an agreement with their union help on the individual contract question. Both sides made some concessions. At present the veteran employees are being paid on a salary basis and are reporting for work daily although the mills are operating only two days a week.

There is no question that the laboring men as a whole are well pleased with the arrangement and the company should be able to retain its best men in this way and so reduce its labor turnover.

Water Service and Wood Preservation Discussed By Railway Men

The week ended March 19 marked a time of importance to the railway technical profession assembled in Chicago. The National Railway Appliances Association at the Coliseum presented exhibits of unusual importance in every phase of the railway field, the railway section of the American Association of Engineers discussed education and salaries and the American Railway Engineering Association held technical sessions at the Congress Hotel.

Among the list of papers presented at the latter meetings and of interest to readers of CHEMICAL & METALLURGICAL ENGINEERING were the reports of the committees on water service and wood preservation abstracted in the following paragraphs.

EXPERIMENTAL EFFECT OF INCRUSTATION ON PIPE LINES

A large proportion of stoppages in pipe lines is due to corrosion, or roughening of the interior surface. Where pipe is well coated before laying trouble of this nature is not generally to be expected with ordinary water for a number of years. This corrosion usually forms the foundation for other deposits by roughening the interior of the pipe. The amount of deposit depends entirely on local conditions.

Mud or suspended matter other than found as a result of water treatment seldom forms a deposit in the pipe unless the foundation has been already laid by corrosion. The amount found depends largely upon the nature of the water and the velocity of the flow. Snails and similar growths are frequently found in suction lines, but little information is to be found on the subject.

Iron, manganese or aluminum promotes the growth of various forms of crenothrix in pipes or reservoirs. There is also a large variety of bacteriological growth known more familiarly as pipe moss, pipe sponge, etc. It is claimed that these organisms will not thrive unless the water is acid. Anything tending to make the water alkaline will reduce or cure the trouble. Filtration may or may not assist. To be of value the filter must be of a nature to remove the bacteria or their food, or both. Many filters fail to remove bacteria, although they may lessen the difficulties.

The usual sequence is for the pipe to roughen through corrosion. Then mud or slime is deposited to form a culture bed for a variety of growths. Incrustation due to water treatment is commonly found in treating plants of various types. This deposit is greatest when the water is under-treated or when raw and treated waters are mixed in the pipe lines. There is also difficulty due to water being used before the reactions are complete. There is no evidence that filters will entirely eliminate incrustation, as a reaction frequently takes place after the chemicals pass the filters. This deposit is usually found in annular rings of various degrees of hardness.

The application of heat will deposit a scale largely composed of the combination of lime and magnesia. In treated water the changes in temperature will also cause a deposit. When the temperature rises in passing from the treating tank, any excess of lime or magnesia will deposit. The reverse is true of soda. As any excess is generally carbonate of lime, the latter is usually the main source of deposit.

The methods of cleaning pipe vary from hand and mechanical treatment to chemical methods. Valves, etc., around treating plants or where treated water is used are usually cleaned by use of hydrochloric acid. The pipe lines can be cleaned by the same process, but the cost is often prohibitive unless chemicals are recovered. It is better to prevent these troubles than to encounter them later.

Prevention may be accomplished by flushing; which is entirely mechanical, and may be used if the local conditions are proper. It will seldom prevent the formation of chemical deposits and will often assist them where raw water is used to flush a line. Aeration before pumping will aid when the water contains iron and produces crenothrix.

The prevention of chemical reactions in the pipe line will as a rule stop all incrustation. It may be said, however, that the better and more complete the water treatment the less the trouble will be. No method has been devised which will eliminate temperature changes and their resultant effect. Pipe cleaning will pay if there is a shortage when the cost of cleaning is less than the cost of an additional pipe line needed for adequate service.

SODIUM FLUORIDE AS A PRESERVATIVE FOR CROSSTIES

Sodium fluoride has been used only in small amounts for experimental purposes. Comparatively small amount is available for preservation of ties at this time. Lack of demand and immediate shortage of high-grade fluorspar have deterred manufacturers in increasing their facilities for its preparation. This recovery of a byproduct from the manufacture of phosphate fertilizer is not being carried out because of the high initial outlay in plant construction and the present conditions of labor and material shortages.

Tests on toxicity of sodium fluoride as made at the Forest Products Laboratory indicate it to be about double that of zinc chloride. Service tests on ties treated with this salt have not been carried on over a period sufficiently long to determine that this same ratio holds true in practice. Until this information is at hand no railroad will go into the extensive use of sodium fluoride for the treatment of ties. Under the circumstances, the comparative prices of zinc chloride and sodium fluoride will determine whether or not the former will be supplanted by the latter, wholly or in part. Recent developments indicate that there is a possibility that sodium fluoride will be obtainable at a price very near that of zinc chloride.

PROTECTION OF PILES IN INFESTED WATERS

The committee presented a paper on the protection of piles in water infested by marine borers. The conclusion was that when piles are used in important structures in infested waters where the best protection is desired they should receive in addition to a thorough treatment with creosote oil some form of mechanical protection best adapted to the conditions.

Further, that generally at points on the Gulf and Pacific Coast creosoted piles should have full length mechanical protection to insure protection against *Limnoria* as well as *Teredo*. At Atlantic coast ports creosote treatment will stop the *Teredo*, but mechanical protection is necessary to resist the *Limnoria*.

Forest Products Laboratory Appropriation Increased

The appropriation for carrying on the work of the Forest Products Laboratory at Madison, Wis., for the coming fiscal year was increased by the last Congress to the extent of \$100,000, or approximately 44 per cent. While this is less than the amount asked for by the Secretary of Agriculture, it is nevertheless a substantial and gratifying recognition by Congress of the needs of the laboratory in carrying on the excellent service it is rendering the industries.

Research on Colorado Clay Resources

The board of directors of the Civic and Commercial Association of Denver has passed a resolution urging the Colorado General Assembly to appropriate \$5,000 for the use of the State Geological Survey in making an extensive investigation of the ceramic resources of the state. This action is based on the report of the Industrial Research Committee which is abstracted below. This study sought to determine the character of the technical investigations which must be made in the ceramic resources to get the attention and confidence of men actually engaged in the industry, as well as to determine the broad economic forces upon which the industry had been built in the great Ohio district in so far as these forces might force a way to a parallel development in Colorado.

The work includes interviews with users, manufacturers, dealers, clay brokers, ceramic experts and officials of the U. S. Bureau of Mines and the Bureau of Standards, all of whom testified to the high quality of clay products made in Colorado.

The general economic forces which have elsewhere built up a localized pottery industry are represented in Colorado's conditions—namely, that the product combines high value with small bulk, and will bear transportation charges; that there are large supplies of coal close at hand; that climatic conditions are such as to overcome the industrial disease tuberculosis. Probably no plant in the United States gets so large a proportion of raw materials so close at hand as does the Coors Pottery at Golden. There are in Colorado large supplies of excellent fireclay, needed in making "saggers."

The progress of the existing Colorado plants shows that clay workers can be trained as they have been trained by the Coors Co., at Golden, by the Western Pottery Co., and by the Denver Terra Cotta Co.

Negotiations are going forward with Prof. R. D. George, looking toward an extensive investigation of ceramic resources of the state, including the availability of raw materials for the manufacture of pottery, especially white ware. Preliminary ceramic tests, fusion and color tests will be made.

Industrial Applications of Colloid Chemistry

Dr. Harry N. Holmes addressed the Connecticut Valley Section of the American Chemical Society at the regular March meeting held at the Hotel Bridgway in Springfield, March 18. His subject was "Colloid Chemistry and Some of Its Industrial Applications."

He exhibited a large number of gels and emulsions, some of the former illustrating crystal growth in such media. One in particular, showing crystals of gold in a silica gel, has attracted much interest among geologists because of the plausible explanation of the occurrence of gold in quartz as being the residue from such an original condition in the earth. According to this hypothesis the gold has crystallized in the gel which has subsequently been dehydrated and the resulting silica has crystallized as quartz.

Prominent among the industrial applications of colloidal chemistry that Dr. Holmes described is colloidal silica as prepared by Patrick, originally for an absorbing medium for gas masks. This new material seems to have a wide field of usefulness on account of its high degree of absorption for certain compounds. At present it is being used to clean up the gases from chamber acid plants and recover oxides of nitrogen as well as escaping SO_2 . Its remarkable affinity for water makes it as good as calcium chloride for drying. A large number of important industrial uses have

been suggested for it and some of them are now in the experimental stage. Among these are its use in drying air for blast furnaces and for absorbing gasoline vapors.

The ceramic industry is now being served by studies of colloids. It is possible to work clay with smaller amounts of water if alkali is added. This means a smaller amount of water to be evaporated and less shrinkage of shaped objects. It is also possible to separate iron from clay to a considerable extent by the addition of the proper amount of alkali, for the clay suspension is stabilized by the acid, while the iron, carrying an opposite charge, is readily coagulated in an alkaline solution and settles out. The use of tannins and other extracts is also being studied.

In the preparation of such emulsions as are used in the manufacture of greases there is a great deal of research for the colloid chemist to undertake. The development of colloidal fuel was also touched on as showing an important application.

Among other problems he listed as important the development of a waterproof glue, a product which the Forest Products Laboratory is interested in because of the probability that in the near future there will be no more big timber and it must be replaced by laminated structures.

He also spoke of the degumming of silk and of wool scouring as important industries to which the study of the colloidal state was necessary to work out improved methods.

The proper disposal of mill waste in general, he said, was very apt to be a problem of getting rid of fine suspensions and a study of the specific problem in the light of present-day knowledge of the colloidal state was often the only way to solve the problem.

Institute of Chemistry

The March meeting of the New Jersey Chemical Society on the evening of the 14th was addressed by Dr. E. Newton Harvey, professor of physiology, Princeton University, on animal light and was illustrated by the production of light from the dried remains of a small crustacean which has this remarkable ability.

Dr. Charles Baskerville, of the College of the City of New York, then told the society of the work which had been done in collaboration with Dr. Gwathmey in the production of anaesthesia without the untoward symptoms associated with the inhalation of ether.

The committee on the possible Institute of Chemistry then presented the following report:

REPORT OF THE COMMITTEE OF THE N. J. CHEMICAL SOCIETY ON A POSSIBLE INSTITUTE OF CHEMISTRY

To the Members of the N. J. Chemical Society:

Your committee prepared a tentative scheme and gave it fairly wide publicity, sending it to the journals and prominent chemists and discussing the matter with many. From the printed and written comments and conversations it appears that there are three groups of opinions.

1. That an American Institute of Chemistry is not needed.

2. That an Institute of Chemistry should exist as an adjunct to or function of the American Chemical Society. No one holding this view points out how the American Chemical Society could so function, we are advised to bring the matter to the attention of the officers and Council, as was done about fifteen years ago.

3. That an Institute of Chemistry, to function, in general, as outlined, is needed; that it should be started by the New Jersey Chemical Society, beginning in New Jersey and showing by experience its advantages and developing working plans adapted to the entire country.

Your committee recommends:

A. Anything done should be handled locally, by the N. J. Chemical Society and not by a new organization.

B. That, in view of the fact that even the simplest listing, etc., will require time and money, the entire matter be referred to the board of governors for further action.

The committee extends to all who have answered its questions their hearty thanks for the interest taken in the matter.

GEORGE T. COTTLE,
C. P. TITUS,
F. D. CRANE, Chairman.

Drafting of Tariff Bill Starts

The Ways and Means Committee of the House of Representatives has begun the work of drafting the permanent tariff bill which is to be submitted to Congress at the extra session. The sub-committee charged with the drafting of the chemical schedules is composed of Representatives Longworth, of Ohio; Copley, of Illinois; and Hadley, of Washington. Mr. Longworth has given specialized attention to chemical matters for many years, but the other members of the sub-committee have made no special study of the subject.

The chemical sub-committee is meeting twice a day. At this writing, attention is being concentrated on testimony from representatives of Government departments. The work has not progressed far enough to permit any definite statement as to plans, but Mr. Longworth states that it is evident that the chemical industries must have more protection than is afforded by a tariff. He states that he is not insisting on his licensing plan, but he believes either that or the selective embargo proposed by the Senate must be resorted to. He expressed the opinion that the chemical schedule, above all others, can justify high rates of duty from the fact that it places very little of the burden on the consumer. As an example, he cited the dye in a suit of clothing. The duty paid on that amount of dye would be insignificant even were the schedule very high.

Mr. Longworth commended very highly the work which has been done by the Tariff Commission. This body has been able to furnish the committee, he said, with very pertinent information on every commodity concerning which members of the committee had inquired.

Dust Explosion Wrecks Chicago Elevator

The Chicago & Northwestern Terminal elevator, leased to the Armour Grain Co., at Torrance Ave. and 122d St., South Chicago, Ill., was wrecked by dust explosion on Saturday, March 19. Of the \$4,000,000 worth of grain in the elevator about \$1,000,000 was lost. Six men on duty also lost their lives.

The view is generally held that the explosion was due to spontaneous combustion of grain dusts and it is also believed that a highly explosive mixture of humid air and grain dust was ignited by a spark possibly from a watchman's cigarette. There could have been no sparks from the machinery, because the explosion occurred at night when machinery was idle.

There were two distinct explosions. The first was a small one, evidently in the driers. This merely acted as an igniter, or detonator, of the main explosion, which passed like a wave of fire through the entire structure. It was announced by the Illinois State fire marshal that complete investigation will be made into the cause of this explosion.

Bureau of Mines May Study Black Hills Ores

A study of the complex sulphides, argentiferous galena in quartz and the blue ores containing gold in sulphides, occurring in the Black Hills region, may be undertaken by the Bureau of Mines under a co-operative agreement with the mining and business interests of that section. There is said to be a large tonnage of refractory ores in the Black Hills which could be mined if improved processes were devised.

Colloidal Clay as Paper Filler

A highly colloidal clay, found in the Rocky Mountain region, has been found by the Forest Products Laboratory at Madison, Wis., to be highly valuable as a loading material for paper. This clay when added to English china clay is said to produce a superior finish and a more velvety quality than when the English clay is used alone.

Stolen Platinum Recovered

The police in Washington report the recovery of the platinum stolen from the Bureau of Standards more than a year ago. A former employee of the bureau was arrested on another charge. A subsequent search of his home led to the discovery of the platinum buried in the cellar.

Chemical Warfare Association Proposed

Plans are being made for the formation of an organization which probably will be known as the Chemical Warfare Service Association. The idea is to take organized steps to acquaint the public with the need for continuing active research and development along the line now being followed. The association would use its influence to secure an adequate proportion of the War Department's appropriations for the Chemical Warfare Service. It would endeavor to co-ordinate the experimentation of this character being done by the Army and by the Navy. The broad thought is to work in the interest of this service, which many believe to embody a more efficient and humane method of warfare and one which gives great advantage to an industrial nation.

The final decision in the matter probably will be reached at the third annual dinner of the Chemical Warfare Service, which will be held in Washington the middle of April.

Book Reviews

CHRONOLOGY OF IRON AND STEEL. Compiled by S. L. Goodale, Professor of Metallurgy, University of Pittsburgh, and edited by J. R. Speer, chairman of the Board, Pittsburgh Iron & Steel Foundries Co. Published by the Pittsburgh Iron & Steel Foundries Co., Pittsburgh, Pa. Price, \$5.

This little book of pocket manual size (4 in. x 6½ in.) contains 300 pages of brief notes on the discovery, development, and perfection of iron and steel making and many related occurrences. Starting with the birth of Tubalcain, "the forger of every cutting instrument of brass and iron," and ending with the death of Andrew Carnegie and Henry C. Frick, men of steel and coke, it mentions a great many names of men of various attainments who have lent their aid in perfecting this most useful aid to civilization, as well as many events in the passing years which resulted not so much from one individual's effort as from the march of events.

All the incidents are arranged according to the approximate date of occurrence. Lacking this information as a starting point, one may consult an alphabetical index at the end.

The compilation is evidently very carefully done, and the book contains a great amount of information which will attract those who are interested in knowing something of the "family tree" of familiar articles made of iron and steel.

E. E. THUM.

CHEMISTRY OF PULP AND PAPER MAKING. By Edwin Sutermeister, chief chemist, S. D. Warren Co. Paper Mills. vii + 479 pp.; 55 figs.; 31 full-page photomicrographs. Price \$6 (33s.). New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 1920.

It is over twenty-five years since Griffin and Little published their "Chemistry of Paper Making." During that time there have been very notable advances in both the pulp and paper industries. The paper industry will, therefore, welcome the contributions of 1920, which include Witham's "Modern Pulp and Paper Making," which deals with the technical and mechanical sides of the industry, and Sutermeister's "Chemistry of Pulp and Paper Making," dealing primarily with the chemical aspects of the industry. The material covered by Sutermeister's book is best seen from the following list of chapter titles: Cellulose; fibrous raw materials: rags, esparto, straw, bamboo; the soda process; the sulphate process; the sulphite process; ground wood or mechanical pulp; bleaching, sizing, loading and filling materials; coloring; coated papers; water; testing wood pulps; paper testing; printing. The author has included all details which the chemist should have to enable him to grasp the methods of manufacture, but the book is in no way a treatise on the manufacturing details of the industry. The work is "written chiefly with the idea of

helping the young technical man, whether chemist or engineer, and it has therefore been assumed that the reader has a fair knowledge of the elements of chemistry."

Sutermeister is particularly well qualified to write such a treatise, since he has been engaged in the paper industry for twenty years, and he has combined the experiences of these years with a careful review of the literature. The industry is peculiar in that there are an unusually large number of variable factors which influence any one operation; it is not surprising, therefore, that the literature should be full of conflicting statements and opinions. In some cases an attempt has been made to reconcile these statements; in other cases both sides of the argument have been presented as fairly as possible. The reader will, therefore, find many lines of investigation indicated throughout the book. Thus in the chapter on bleaching the following are some of the problems indicated: "The conclusion that slight washing is not likely to prove injurious to the durability of the paper is counter to the generally accepted theories, but from the above experiment (p. 247) no other conclusion can be reached." "The folding and bursting strength of sulphate is not injured by bleaching . . ." Under the chapter on rosin the question is again raised regarding the use of so-called wood rosin in paper sizing. This apparently is not an entirely reliable method, but more conclusive tests should be carried out. Another question on sizing is the relation between the manner of drying and the sizing of the sheet. These are only a few of the many research problems that the paper maker will find as he carefully reads the book.

The book is well written and illustrated, and is well executed mechanically. The photomicrographs of the typical paper-making fibers and of the loading and filling materials, prepared by the Bureau of Standards, add much to the value and appearance of the work.

The pulp and paper industry is to be congratulated on this addition to an altogether too scanty scientific literature of the art.

CLARENCE JAY WEST.

Personal

Dr. E. Q. ADAMS, of the staff of the Bureau of Chemistry, has tendered his resignation and will take a position in the Nela laboratory of the National Lamp Works at Cleveland.

H. A. BERG, superintendent of blast furnace operations of the Midvale Steel & Ordnance Co. at Johnstown, Pa., has been appointed to succeed W. A. Maxwell, Jr., as assistant general superintendent of the Cambria Steel Co., Johnstown, Pa., the latter having resigned to accept the position of general superintendent of the Inland Steel Co., Indiana Harbor, Ind.

Dr. HENRY C. BOYNTON, metallurgist at the plant of the John A. Roebling's Sons Co., Trenton, N. J., gave an interesting address recently before the members of the local Rotary Club on the subject of the "Evolution of Wire Rope." The talk was illustrated with lantern slides.

R. B. BROWN, superintendent of the Chicago plant of the Sherwin-Williams Co., spoke before the Chicago Chemists Club recently, on the application of chemistry to paint and varnish industries.

A. E. DRUCKER, professor of metallurgical engineering at the Wisconsin School of Mines, went to the University of Illinois Feb. 1 as assistant professor of mining engineering.

Dr. GUSTAV EGLOFF was in New York for a few days last week.

F. C. FAIR has been placed in charge of the new chemical laboratory established by the Railway Signal Co., Hammond, Ind. This company has headquarters at Pittsburgh and manufactures fuses and torpedos for signaling on railroads.

WALTER J. GELDARD recently resigned as chief of the analytical section, Fixed Nitrogen Research Laboratory, and

has accepted a similar position with the International Coal Products Corporation of Newark, N. J.

WALTER F. GRAHAM has resigned as metallurgist with the Spicer Manufacturing Co., Plainfield, N. J., and is now associated with the Henry Souther Engineering Co., Hartford, Conn. Mr. Graham was formerly associated with the late Henry Souther as metallurgist for the Standard Roller Bearing Co., and subsequently with the Ferro Machine & Foundry Co. and the Ingersoll-Rand Co.

CHARLES HORVATH, research chemist for the International Motor Co., New Brunswick, N. J., resigned some months ago to become chief chemist for the National Metal Reduction Co., Newark, N. J., and the Atlantic Smelting & Refining Works of New York City, the plants of which are located in Newark.

J. C. INGRAM, who has for the past four years been chemical engineer in charge of the refinery, oil and soap division for the American Cotton Oil Co., Chicago, has resigned to accept a position as development engineer with Morris & Co. Mr. Ingram's activities will have to do with developing production problems through scientific application at the Chicago packing plant.

H. E. LABOUR, until recently president of the Chemical Equipment Co., has severed his connection, effective March 15, and will remain in Chicago, opening a consulting and sales office.

Major J. C. MILLS has joined the staff of the Chemical Warfare Service as chief chemical adviser to General Fries. During the war Major Mills went to France with the first gas regiment. He was one of the mainstays of the service throughout the struggle. To accept his present position, Major Mills retired from the faculty of the University of North Carolina.

Dr. R. B. MOORE, the chief chemist of the Bureau of Mines, will address the New York Section of the American Electrochemical Society on April 8. In view of the forthcoming visit of Mme. Marie Curie, he has chosen radium as his subject.

A. V. H. MORY, who has recently severed connections with Procter & Gamble Co., Cincinnati, Ohio, is associated with William Hoskins at 111 W. Monroe St., Chicago, on consulting work.

Dr. H. T. NIXON, formerly chief chemist at the Argentine refinery of the Sinclair Refining Co., recently resigned to become chief chemist for the C & C Developing Co., Kansas City, Mo., which concern applied the Cherry process for producing synthetic gasoline.

Dr. ARNOLD H. SMITH resigned his position as research chemist with the Goodyear Tire & Rubber Co., to assume the position of chief chemist with the Thermoid Rubber Co., Trenton, N. J.

Obituary

JAMES B. BROAD, Wilmington, Del., comptroller for E. I. du Pont de Nemours & Co., died March 13, at the Homœopathic Hospital from lung infection, caused by swallowing a tooth during a dental operation. He was forty-three years of age and had been connected with the company in various capacities since 1904. He became comptroller in 1918.

Dr. FRANK W. GUNSAULUS, president of Armour Institute, died March 17 at the age of sixty-five. He was stricken suddenly with heart disease and passed away two hours afterward at his home, 2919 Prairie Ave., Chicago, Ill.

JACOB HASSLACHER, founder of the firm of Roessler & Hasslacher, died on March 15 at his home in New York City. Born at Ems-am-Lahn, Germany, in 1852, he came to New York in 1884, and within five years started a most successful and influential career. Mr. Hasslacher leaves a widow, Mrs. Elizabeth Fleck Hasslacher; two sons, George and Carl, and four daughters, Misses Agnes, Toni, Thea and Emily.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, March 28, 1921.

There was no particularly marked improvement in the demand for chemicals during the past week. Intervals of buying have been followed by periods of extreme dullness; nevertheless, business in general is a shade better compared with the past few weeks. Expansion promises to be slow but steady and there is little in the present situation to inspire any strong optimistic tendencies. Perhaps it is better that it is so as there will be fewer vain regrets arising from the danger of an overextension of trade expansion. There were persistent reports from several directions of curtailed chemical production, while in some cases production has been temporarily suspended, as there is enough stock in second hands to take care of the demand at lower prices than producers can name. This condition is true among leading manufacturers of caustic soda. It is generally agreed that the peak of depression has passed, but how soon business will pick up is a problem only time can solve. Reductions in overhead and operating expenses are being made quite generally and seem to be working temporary hardships in many cases, but in the long run are expected to bring lower prices and normal conditions.

OTHER MARKETS STAGNANT

In trying to analyze the chemical market, it is well to look into other markets, as conditions are practically similar and a great deal rests upon the materialization of developments there. The primary and wholesale markets, which for a time have shown a spotty improvement, have in many cases become dormant again. Railway traffic and earnings are decreasing continually. Steel output has fallen to less than one-half of mill capacity. Production of coal has fallen to the lowest point in the past few years and building operations are lagging far behind the total of new construction known to be in immediate demand. Moderate liquidation from the reserve banks is reflected in the slight improvement in the reserve ratio of the federal reserve system, although a substantial part of this improvement is the result of gold importations which have continued uninterruptedly for the past year. Buyers as a result of existing conditions remain unwilling to contract for other than immediate necessities, which are at an extremely low figure.

The passing of the payment of the income tax for 1920 was a favorable feature. This had an unusually quieting effect on the chemical trade, but business seemed to become brisk again shortly after. The disposition on the part of some interests to sell English soda ash at \$1.90 per 100 lb. ex dock N. Y. is being watched very cautiously. Caustic soda held well owing to the suspension of production and consuming orders came into the market in better volume than in the past month. Business has been placed with a few textile and soap plants.

Reports from various quarters in the New England States show that textile mills are averaging about 70 per cent normal output. Some plants are operating at full capacity, while others have found the road harder to travel on account of the keen competition and have been unable to accomplish much more than one-half their total capacity production. With fall prices completed, the woolen industry seems to have improved and several American Woolen Co. plants have resumed operation on full-time schedule. Reductions in wages and lower prices for finished products are the principal factors responsible for the noticeable improvement among these mills. Reports from leading Western chemical producers were more optimistic than from local points.

Standard brands of *caustic soda* appear to be well held at the present time. Buyers demanding special makes are finding a stiff market. The general range was from \$3.70 @ \$3.80 per 100 lb. ex-warehouse and \$3.80 @ \$3.85 f.a.s.

Occasionally arrivals from interior points go at a slight concession, while outside makes can be purchased in the neighborhood of 3½c. per lb. Resale light *soda ash* is generally quoted at \$1.95 @ \$2.05 per lb. in single bags. Offerings of English material have left the market in a somewhat unsettled condition. The feeling is prevalent in the trade that producers will be forced to meet foreign competition, but as yet they have failed to do so. Barrels are quoted from \$2.10 @ \$2.25 per 100 lb., according to quantity. Contract prices remain unchanged at \$1.72½ per 100 lb., basis 48 per cent, in carlots f.o.b. works.

Imported 88-92 per cent *caustic potash* is offered at 10c. per lb. with odd lot sales noted down to 9½c. per lb. A peculiar position exists in this market due to the fact that the 70-75 per cent KOH is selling at a higher figure than the stronger variety. Exporters bought the 88-92 per cent almost exclusively during the past year and with the recent slump in the foreign markets all this material was reshipped to American ports and dumped into the market. Leading factors in *chlorate of potash* are asking 10 @ 12c. per lb. for prime American material. It is stated that a cheap lot of imported stock has been taken off the market. There are enough stray lots, however, that still can be purchased all the way down to 8c. per lb. The better grades of imported material are offered at 9 @ 10c. per lb. Small quantities of *yellow prussiate of potash* are being offered by dealers at 25 @ 27c. per lb. The red variety is in small supply, with the market quoted around 50c. per lb. Fused 60-62 per cent *sodium sulphide* is quoted at 5¼ @ 5½c. per lb. by second hands. The crystals, 30 per cent, are very scarce at present and buyers are finding difficulty in covering requirements of spot material. Spot *citric acid* is quoted firm, with sales at 47c. per lb. and sellers asking up to 48c. Continued strength prevails in the foreign market and 42c. per lb. for shipment from abroad is considered a very close figure. Some real business has recently been placed at these levels and the market for the coming season looks exceptionally favorable for early buying at the low prices.

A continued quiet inquiry for *bichromate of soda* has had a depressing influence on spot quotations during the past week and the market closed easy with a moderate amount of resale material of standard quality offered at 7½c. per lb. The range was from 7½ @ 7¾c. per lb., according to quantity. While resale stocks are not described as heavy, it is asserted that unless the demand improves a lower trading is likely to be established. Prices on *ammonium chloride* continued rather uncertain in the absence of any noted demand. Imported material is still to be had in good volume at prices well below those named by domestic producers. White granulated *sal ammoniac*, imported, is offered at 7½ @ 8c. per lb., with domestic prices around 10c. The gray variety is to be had at 8 @ 9c. per lb. A continued lack of interest has forced further recessions on *ammonium sulphate* and offers are now heard at \$2.75 @ \$2.85 per 100 lb. in single bags. Double bags for export are quoted down to 3c. per lb. Leading makers of *calcium acetate* are quoting on the former basis of \$2 per 100 lb., but there are offers in the market from outside manufacturers as low as \$1.50 per 100 lb. The weakness of acetic acid has prevented strength in this item.

According to figures on foreign trade recently issued by the Department of Commerce, increased imports and decreased exports in February as compared with January are shown in the following table:

	February, 1921	January, 1921
Exports	\$489,000,000	\$655,000,000
Imports	215,000,000	209,000,000
Totals	\$274,000,000	\$446,000,000
	February, 1920	January, 1920
Exports	\$5,127,000,000	\$5,230,000,000
Imports	2,757,000,000	3,235,000,000
Totals	\$2,370,000,000	\$1,995,000,000

COAL-TAR PRODUCTS

Although there was a difference of opinion expressed in various quarters on the action of the coal-tar products market, there surely was an expansion noted on the part of consumers and also on the volume of trading. Sales were confined to limited quantities, as the future needs are not being anticipated.

Intermediates have shown very little change during the week and while most producers have held quite close to last week's prices, there has been a tendency toward shading on firm business. There still seems to be quite a few resale lots of intermediates offered on the market, but the prices at which they were quoted did not reveal any marked concessions under prevailing levels. A fair volume of inquiries was noted, on the other hand, and in view of the fact that plants are producing on a smaller scale a scarcity of some commodities will eventually show on the market.

The crude market held steady and prices have practically shown no noticeable change, except in naphthalene flakes and balls, which are a trifle firmer in view of the more active demand at this time of the year.

Supplies of *diethylaniline* are available in fair volume in some directions. There has been very little interest shown by consumers, other than a quiet routine movement of small quantities. Prices ranged from \$1.25@1.30 per lb. The demand for *alpha naphthol* during the week has been very light and while the level of prices holds fairly steady for the crude at \$1.20 per lb, shading is possible in second hands at \$1.10@1.15. The position of *beta naphthol* seemed to be a trifle weaker, although quite a few factors claimed a better demand. First hands are firm in their views and quote the market at 40@43c. per lb. Resale material is available in fair volume down to 33c. per lb. Resale offerings of *paranitraniline* continue around 85c. per lb., but producers are still unwilling to sell below 95c.@\$1.05 per lb. for spot or prompt shipment. Makers are rather inclined to doubt the quality of resale material which has been out of their hands for some time. Contracts are offered by manufacturers at \$1.15 per lb., although shading is quite possible on firm business.

The Chicago Market

CHICAGO, March 25, 1921.

Quiet conditions still prevail in the market for industrial chemicals. Reports from some quarters indicate that a fair volume of business is being done, although only in small packages. Consumers are still adverse to anticipate and are buying only for their immediate requirements.

Soda ash, 58 per cent, continues to be firm and is quoted in barrels at \$3.10 per 100 lb. for small quantities. *Caustic soda*, 76 per cent, is quoted as high as \$4.25 per 100 lb. in ton lots. *Salsoda* is moving in a small way at 2½c. per lb. *Bleaching powder* is very dull, and is quoted at 3½c. in 700-lb. drums.

Producers' agents are offering *formaldehyde* at 16½c. and are doing considerable business at this figure. Most of the resale material is now out of the market and the first hands are again able to compete. Spot *potassium chlorate* crystals are available at 13c., but most factors report little business. *Caustic potash*, 88-92 per cent, is quoted in 700-lb. drums at 11½c., but with actual business in sight this could probably be bettered. *Potassium carbonate*, 80-85 per cent, is offered at 15½c. in casks. *Glycerine*, c.p., is lower and refiners now quote 18c. per lb. in drums. The new level for non-beverage *ethyl alcohol* is \$4.85 per gal. in single drums, and is moving in a fair way. The continued mild winter has had its effect on the *denatured alcohol* market, distillers quoting 40c. per gal. in five-drum lots on the 188 deg. proof completely denatured, while a wide range of prices can be obtained from resellers. *Wood alcohol*, 95 per cent, continues weak, and is quoted at 85c. in barrels, or 77c. in drums.

Quicksilver is very quiet and is quoted from \$48@\$52 per flask. *Ammonia*, 26 deg., is available at 7½c. in drums. White granular *ammonium chloride* is offered at 11½c. in single barrels, but very little is moving. Imported *barium chloride* is offered at \$80 per ton in cask lots. Some interests report a fair volume of small business in *lead acetate*, white crystal, at 15c. per lb. Spot *sodium dichromate* can be had at 9½c., with somewhat better prices on material for prompt shipment from the works. *Potassium dichromate* is offered to arrive at 16c., but it is doubtful if much business could be done at this figure.

The general list of acids is firm and quiet, with the exception of *acetic acid*. The *glacial* is now offered by makers at \$11.25 per 100 lb. in lots of fifteen to twenty barrels.

The 28 per cent is moving in a very fair way at 2½c. in barrels and 3½c. in carboys. *Muriatic acid*, 18 deg., is offered at from 1½@2½c., depending upon the quantity. *Sulphuric acid*, 66 deg., is quoted around \$20 per ton, but, like the rest of the list, is very quiet. *Oleum* can be had for \$3.10 per 100 lb. in drums. Imported *oxalic acid* is offered on spot at 19½c. in single casks, while producers continue to quote 25c. for the domestic.

VEGETABLE OILS

The vegetable oil market is extremely quiet and business in most of the oils is confined to unusually small parcels. The trade appears to have adopted a waiting policy and buyers are holding off pending developments in the general situation. *Coconut oil* is quoted at 10½c., but very little is moving. *Linseed oil* is offered at 69c. in single barrels, but, owing to the quietness in the paint trade, very little is being sold.

NAVAL STORES

Conditions in the local naval stores trade have undergone little change and a quiet tone was reported in all quarters. *Turpentine* is quoted at 58c. in drums, the demand being light. *Rosin* is offered at \$7.35 for the WG with corresponding prices for the other grades.

COAL-TAR PRODUCTS

Business in coal-tar products is still very dull, although encouraging reports are heard in some quarters. There is an ample supply of *benzene* available at 31c. per gal. for the 90 per cent and 33c. for the 100 per cent in lots of one to ten drums. Refined *toluol* can be obtained for 33c. per gal. There is little demand for *naphthalene flakes*, which are being held on spot for 10½c. in small lots.

The Iron and Steel Market

PITTSBURGH, March 25, 1921.

The slight improvement in demand for steel products noted a week ago has grown. There is distinctly noticeable a greater call for steel products, particularly for merchant bars, standard steel pipe and sheets. The week's news of structural work shows a larger tonnage, but this may prove ephemeral. In the other products mentioned the call is widespread, there being numerous small lots.

Careful scrutiny does not indicate that the increased call for steel is a seasonal affair, due to the arrival of spring. Rather it is due to the technical condition of the trade, there having been for weeks a particularly rigid curtailment by all buyers, while they reduced inventories. Such an extreme lightness of demand could not continue indefinitely, as it was far below the rate of actual consumption.

The total of demand now, however, is still small. There is merely improvement in the rate. Absolutely fresh buying remains very light, the improvement in the call for material being chiefly by way of releases on orders, shipment against which had been held up. The rate of production of steel continues to decline, shipments having been in excess of specifications and orders, and a further decline in production is to be expected in the next few weeks, until demand increases sufficiently to effect a turn.

The United States Steel Corporation's production last week, measured by ingots, was about 49 per cent of capacity. This week production is slightly less, probably about 45 per cent. The common estimate now is that the independents are operating at 20 per cent or less. These percentages would make rates of production of 10,000,000 tons of ingots a year by the Steel Corporation and 6,000,000 tons by the independents, the 16,000,000 tons being 30 per cent of the present estimate of capacity or 53 per cent of the average rate in 1912 and 1913, the two best tonnage years before the war, when there appeared to be a widespread demand for steel products for practically all employments. Now there appears to be scarcely any consumption, and from this viewpoint the actual production is high rather than low.

PRICES

On carload lots with fairly desirable specifications bars are still quotable at 2c. and shapes and plates at 2.10c. Concessions possible from these figures for really large lots

are if anything smaller than obtainable a month ago. Black sheets remain at 3.85c. for carload lots with desirable specifications. Galvanized sheets in carload lots may be quoted at 4.90c., or \$2 a ton less than a week ago. The spread of 1.05c. between black and galvanized is equal to the average spread in the ten years before the war. Zinc is considerably lower, while wages are higher.

STANDARD STEEL PIPE LOWER

Standard steel pipe has now joined the list of steel products on which Industrial Board or Steel Corporation prices are shaded. Several independent mills now quote an extra 2½ per cent in addition to the customary trimmings from the published list, which has a basing discount of 57½ per cent. It is reported that in some cases an extra 5 per cent is given, the extra discounts representing approximately \$2 and \$4 a ton respectively from the prices hitherto held. It is reported that several mills have put out a price guarantee.

Tin plate is now the only important steel product in the independent market remaining at the Steel Corporation or Industrial Board price. Tin plate is held at the \$7 price chiefly perhaps because mills recognize that if cutting once began it could not be stopped.

STEEL CORPORATION POSITION

The wisdom of the Steel Corporation's continued policy of maintaining its prices is being more generally commended. It is plainly seen that price reductions do not bring out additional business, that consumers do not wish to make commitments at this time, and that indeed many buyers prefer to see prices maintained, as facilitating their disposal of material already on hand. That the Steel Corporation will eventually reduce its prices, and will reduce them quite sharply, is commonly believed. Opinion differs as to whether the corporation will reduce prices first and wages afterward or will act on both subjects at the same time. It seems improbable that the corporation will maintain present prices and wages longer than until May 1.

PIG IRON

Sufficient movement of basic pig iron out of stocks of steel interests has occurred to force recognition of the steel works as making the pig iron market. Steel interests have sold basic at \$23 valley, and are willing, even anxious, to sell more at the same price. The merchant furnaces continue to quote their former price of \$25, which is below their recent or even present cost of production, including overhead, but the steel interests can probably figure that iron sold at \$23 can later be replaced at a lower cost, without allowance for overhead. Bessemer remains quotable nominally at \$27 valley, but it is understood that it has been offered in limited quantities by dealers at \$25. Foundry iron, recently quotable at \$26 valley, can now be had at \$25.

SEMI-FINISHED STEEL

There are dilettante negotiations between sheet mills and steel mills on sheet bars. The sheet mills do not make bids, and do not close when offered sheet bars at \$38. Standard billets are nominally at the same price as sheet bars. Small billets have been quoted at \$40.

STEEL PROSPECTS

The volume of demand for steel in the next few months is regarded as hingeing chiefly upon two factors, the matter of German reparations and the attitude of labor in the building trades. Settlement of the reparations question would greatly improve general sentiment and would probably stimulate business to an extent. Reductions in the wage scales of the building trades would in all probability materially stimulate building, which is now at a low ebb. That any very large tonnage demand for steel would be created by a wave of dwelling house construction is obviously improbable. The large consumption of steel lies rather in hotel and skyscraper buildings and in power development. The oil country demand for tubular goods may easily revive. Oil prices are down, but if the cost of drilling is correspondingly reduced the oil industry will be more promising than in 1920.

Solvent naphtha, water-white, in drums, 100 gal..... gal.	.28 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.16 — .18
Sulphanilic acid, crude..... lb.	.30 — .35
Tolidine..... lb.	1.35 — 1.45
Toluidine, mixed..... lb.	.40 — .45
Toluene, in tank cars..... gal.	.28 — .32
Toluene, in drums..... gal.	.30 — .35
Xylidines, drums, 100 gal..... lb.	.40 — .45
Xylene, pure, in drums..... gal.	.42 — .45
Xylene, pure, in tank cars..... gal.	.45 — .45
Xylene, commercial, in drums, 100 gal..... gal.	.33 — .35
Xylene, commercial, in tank cars..... gal.	.30 — .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 — \$0.26
Beeswax, refined, light..... lb.	.27 — .28
Beeswax, white pure..... lb.	.40 — .45
Carnauba, Florida..... lb.	.68 — .70
Carnauba, No. 2, North Country..... lb.	.30 — .32
Carnauba, No. 3, North Country..... lb.	.18 — .19
Japan..... lb.	.19½ — .20
Montan, crude..... lb.	.07 — .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03½ — .03½
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02½ — .03
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 — .04½
Paraffine waxes, refined, 125 m.p..... lb.	.04½ — .05
Paraffine waxes, refined, 128-130 m.p..... lb.	.05 — .06
Paraffine waxes, refined, 133-135 m.p..... lb.	.06 — .06½
Paraffine waxes, refined, 135-137 m.p..... lb.	.06½ — .06½
Stearic acid, single pressed..... lb.	.11 — .11
Stearic acid, double pressed..... lb.	.11½ — .11½
Stearic acid, triple pressed..... lb.	.12 — .12½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.70
Pine oil, pure, dest. dist..... gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.37
Pinewood creosote, ref..... gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl..... 280 lb.	\$5.50 —
Rosin E-I..... 280 lb.	5.75 —

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

GOLDEN—The Colorado Feldspar, Flint & Mica Co., Denver, Col., has preliminary plans under way for the construction of a new plant at Golden, to comprise a complete crushing and grinding mill.

Connecticut

BRIDGEPORT—The American Tube & Stamping Co., Stratford Ave., has filed plans for the erection of a new 2-story laboratory building, 30 x 40 ft. It will be used for chemical, physical and other experimental work, divided into seven departments.

Georgia

SAVANNAH—The Atlantic Turpentine & Pine Tar Co., Central Junction, near Savannah, is planning for the rebuilding of its plant recently destroyed by fire. The loss is estimated at \$150,000, instead of \$75,000, as previously announced. D. S. Owen is manager.

Idaho

WEISER—The Idaho Clay Products Co. is planning for the early erection of its proposed new local branch plant, to be located at clay properties near the city.

Indiana

HARTFORD CITY—The Fort Wayne Corrugated Paper Co. is making a number of improvements in its local plant during a curtailment period, and plans for the resumption of operations at an early date.

WINAMAC—The Winamac Cement Product & Construction Co. has been organized to take over the cement tile manufacturing plant of the Winamac Tile Co. The new company is said to be planning for a number of improvements in the plant. It is headed by Christopher Hanson, George and John Kenzick.

SUMMITVILLE—The Crystal Glass Co. has awarded a contract to the L. J. Drummond Co., Elwood, Ind., for extensions and improvements in its plant. A number of new gas producers, tanks and other equipment will be installed.

Kentucky

LOUISVILLE—The Magic Soap Co., recently organized, has acquired the property of the Magic Soap Products Co. at a receiver's sale for a consideration of \$160,000. The new company will continue the operation of the plant and is said to be planning for a number of improvements. M. O. Curd is president and L. L. Daugherty treasurer.

Louisiana

SHREVEPORT—The United States Window Glass Co., Morgantown, W. Va., will increase the size of its proposed new plant at Jewella, near Shreveport, with total investment of over \$2,000,000 instead of about \$1,000,000 as previously arranged. Plans are under way for the plant and it is expected to inaugurate operations at an early date. Walter A. Jones is president.

NEW IBERIA—The Charles Boldt Pulp Co., has awarded a contract to the Mac-Cabe Construction Co., Cincinnati, Ohio, for extensions in its plant to cost about \$40,000.

Maryland

FAIRFIELD—The Prudential Oil Co. has acquired about 30 acres of property at Fairfield, in the vicinity of its present works, known as the Bowles property, for the erection of a number of extensions. Plans for the work are under way.

BALTIMORE—The United States Industrial Chemical Co., Curtis Bay, is completing plans for the proposed extension to its plant at Stonehouse Cove, consisting of a building 60 x 130 ft.

Massachusetts

HOLYOKE—The Paper City Mfg. Co., Rackliffe Bldg., has acquired the building of the Ferguson Laundry Co. at a public sale, and will utilize the structure for proposed extensions. It was secured for a consideration said to be \$16,000.

New Jersey

NEWARK—The Franklin Baker Oil Co., Diremus Ave., is said to be planning for the early rebuilding of the portion of its plant, destroyed by fire March 10, with loss estimated at about \$100,000. The company specializes in the manufacture of coconut oils.

TRENTON—The American Rotex Mfg. Co., Cleveland, O., manufacturer of imitation leather products, has acquired the plant of the Trenton Lamp, Brass & Copper Works, New York Ave. and Mulberry St., more recently occupied by the Cosmic Chemical Co., for a consideration said to be about \$100,000. The plant consists of a group of six large buildings with power plant, and the different structures will be remodeled at a cost of about \$30,000 to accommodate the new industry. Machinery and equipment estimated to cost about \$100,000 will be ordered and installed at an early date. Offices will be established at the plant site at once. A. M. Mander is president; P. F. Wills is representative of the company in charge.

CLAYVILLE—The L. G. Nester Co., recently incorporated with a capital of \$50,000 to manufacture glassware, has plans under way for its proposed new plant on local site. Lyman G. Nester is head.

TRENTON—Fire, March 16, destroyed a portion of the plant of the Ewing Rubber Co., Homan and Hilton Aves., with loss estimated at about \$15,000. It is said that the plant will be rebuilt. George H. Royle is head.

NEWARK—The Celluloid Co., 290 Ferry St., will use a considerable portion of the proceeds of its recent capital increase of \$4,000,000 for plant extensions and improvements. During the year just past the company expended a total of \$1,300,000 for work of this character and it is proposed to continue this expansion program. Marshall C. Lefferts is president.

CAMDEN—The Russell Products Co., Sixth and Jackson Sts., manufacturer of paper specialties, is arranging for the rebuilding of the portion of its plant recently destroyed by fire with loss of about \$15,000.

JERSEY CITY—James H. Rhodes & Co., South Albany Ave., Chicago, Ill., manufacturer of industrial chemicals, has purchased the 2-story factory, 100 x 200 ft., at 34-40 Liberty St., for use as a branch works. The structure heretofore has been held by the Foot Mfg. Co., manufacturer of polishing buffs, felts, etc.

New York

BUFFALO—The Dunlop Rubber Co., River Rd., is planning to inaugurate operations at its new local plant for the manufacture of tires and other rubber goods on April 15, giving employment to about 1,000 operatives. This number will be increased until the working force totals about 5,000 persons before the close of the year. The plant when entirely complete will represent an investment of about \$20,000,000.

MALONE—The Northern Process Co. has awarded a contract to Henry I. Jones, Grove St., for the erection of a new 2-story and basement plant, 35 x 140 ft., to cost about \$60,000, forming an addition to its present works.

North Carolina

CHARLOTTE—The American Progressive Sales Co., Asheville, N. C., is planning for the erection of a plant at Charlotte for the manufacture of cement and clay building products. S. F. Roberts is manager.

GREENSBORO—The Armour Fertilizer Works, Chicago, Ill., is planning for the early operation of its new acid works now nearing completion, representing a cost of about \$250,000. The plant will be operated

for the production of sulphuric acid for use at the company's fertilizer works at this same place.

Ohio

DEFIANCE—The Farmers' Sugar Co. is having plans prepared for the construction of a new sugar mill on local site, to consist of a number of 1-, 2- and 3-story buildings, estimated to cost about \$1,000,000 with machinery. A. H. Smith, 215 Nasby Bldg., Toledo, O., is engineer. Charles H. Allen is president.

WILLIARD—The Pioneer Rubber Co. has completed plans for the erection of the proposed new 2-story addition to its plant, 63 x 160 ft., and will soon call for bids. It is estimated to cost about \$50,000. A number of homes for employees will also be constructed. Granville E. Scott, Norwalk, Ohio, is architect. B. O. Smith is president.

Oklahoma

MUSKOGEE—The Muskogee Cotton Oil Co., 724 Mill St., is planning for the rebuilding of the portion of its plant recently destroyed by fire with loss estimated at about \$15,000. George H. Walker is president.

TULSA—The Phanotax Chemical Co., recently removed to Tulsa from Memphis, Tenn., has acquired a half block of property on Fourth St., between Frankfort and Elgin Sts., 150 x 300 ft., for the erection of a new 7-story and basement building, a large portion of which will be given over to chemical and chemical byproduct manufacture. The new plant is estimated to cost about \$400,000 with equipment.

LAWTON—The Damascus Refining Co., Cleveland, O., is perfecting plans for the erection of its proposed new plant at Lawton for the manufacture of waxes to be used for lubricating oil production. W. G. Black is president.

Ontario

TRENTON—The Chemical Products Co. is having plans prepared for the erection of a new plant for the manufacture of fertilizer products, to consist of three buildings, each 1 story, 80 x 220 ft., 60 x 120 ft. and 50 x 50 ft., estimated to cost about \$500,000 with machinery. The Austin Co., 16122 Euclid Ave., Cleveland, O., is in charge. A. H. C. Hartman is head.

Oregon

PORTLAND—The Portland Vegetable Oil Mills has inaugurated preliminary work on its proposed new local plant, to be located on a portion of the site previously used by the Foundation Co. as shipyard property. Actual construction of the new mills will be started early in April. The plant is estimated to cost about \$450,000 with machinery.

OREGON CITY—T. B. McBain and associates, Oregon City, are perfecting plans for the construction of a new local paper mill.

Pennsylvania

PHILADELPHIA—The Rinold Brothers Paint Works, Inc., has taken title to the 2-story brick factory on Grove St., near Wharton St., 50 x 314 ft., for a local plant. The site was secured for a consideration said to be \$43,000.

KANE—The Interstate Glass Co., Bradford, Pa., has plans under way for extensions and improvements at its plant at Kane, to cost about \$70,000. H. J. Walters is head.

Texas

BRECKENRIDGE—The Shamrock Oil Corp. has plans under way for the erection of the initial unit of its proposed new casinghead gasoline plant. Construction will be inaugurated at an early date.

West Virginia

HUNTINGTON—The West Virginia Glass Mfg. Co. is planning for the erection of a number of additions to its plant to double, approximately, the present output. New automatic blowing machines and auxiliary operating equipment will be installed. The plant specializes in the manufacture of glass jars and has a present capacity of from two to three cars a day. The expansion is estimated to cost about \$75,000. B. G. Landau is general manager.

Wisconsin

MILWAUKEE—The building occupied by the Frazer Paper Co., National Belting & Salvage Co. and kindred industrial interests was destroyed by fire March 17, with total loss of about \$130,000, distributed among the companies.

New Companies

THE WEST CHEMICAL CO., 313 South Clinton St., Chicago, Ill., has been incorporated with a capital of \$30,000 to manufacture chemicals and chemical byproducts. The incorporators are A. B. Rosenfeld, Abraham Jacobson and Abraham M. Gordon.

THE WINOIL SUPPLY CO., Passaic, N. J., has been incorporated with a capital of \$100,000 to manufacture refined oils and affiliated products. The incorporators are John Hanley, Thomas E. Duffy and Peter J. Wynne, 185 Jefferson St.

THE IDOLA CHEMICAL MFG. CO., New York, has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are T. J. O'Hanlon, J. Reusch and C. Massingill, 152 Madison Ave.

LEVEISEUR, HAROTH & CO., INC., Boston, Mass., has been incorporated with a capital of \$100,000 to manufacture leather products; the company will operate a tannery. The incorporators are Frederick J. Leviser, A. W. Hull and Alfred W. Haroth, 8 Stratford Rd., Melrose, Mass.

THE CERAMIC PRODUCTS CO., 175 West Jackson Blvd., Chicago, Ill., has been incorporated with a capital of 75,000 to manufacture pottery and other fine ceramics. The incorporators are William C. Danms, Walter W. Weiss and E. S. Radcliffe.

THE AMERICAN LABORATORY PRODUCTS CO., Cleveland, O., has been incorporated with a capital of \$2,000,000 under Delaware laws, to manufacture chemicals and chemical byproducts. The incorporators are H. Linsdale Smith, W. C. Husted and G. S. Patterson, Cleveland.

THE RAVENSWOOD PORCELAIN CO., Ravenswood, W. Va., has been incorporated with a capital of \$50,000, to manufacture porcelain products. The incorporators are Charles W. Turnbull, New Haven, W. Va.; J. H. Camp and J. W. Hall, Ravenswood.

THE HIMMER BROS. CO., INC., 1221 East Monument St., Baltimore, Md., has been incorporated with a capital of \$20,000 to manufacture paper products. The incorporators are John C. and Charles Himmer and John H. Renner.

THE AMPROCO CO., New York, has been incorporated with a capital of \$10,000 to manufacture chemicals and chemical byproducts. The incorporators are S. R. Barrett, and C. F. and L. T. Glendhill, 684 East 19th St., Brooklyn.

THE MARVELLUM CO., Holyoke, Mass., has been incorporated with a capital of \$15,000, to manufacture paper products. The incorporators are R. S. Bracewell, George E. Senseney and Francis C. Heywood, Holyoke.

THE SANITARY CHEMICAL SPECIALTIES CO., 208 North Wells St., Chicago, Ill., has been incorporated with a capital of \$15,000, to manufacture chemicals. The incorporators are Walter H. Shryock and J. W. and Arthur C. Tretow.

THE WESTERN NEW YORK PAPER CO., Rochester, N. Y., has been incorporated with a capital of \$15,000, to manufacture paper specialties. The incorporators are C. H. Mason and G. and J. Doyle, Rochester.

THE HIGH GRADE LARD & COMPOUND CO., INC., 2600 Hafer St., Baltimore, Md., has been incorporated with a capital of \$25,000, to manufacture lards and compounds. The incorporators are Max Baker, Robert Plein and William E. Bragg.

THE TEXTILE LEATHER & METAL PRESERVER CO., Kalamazoo, Mich., has been incorporated with a capital of \$100,000, to manufacture compounds and chemical preservatives for textiles, leather and metal products. The incorporators are Clarence D. Shaffer, and Willard R. Sparks, Kalamazoo; and Elbert W. Sweet, Benton Harbor, Mich.

THE SIGNAL MOUNTAIN PORTLAND CEMENT CO., Atlanta, Ga., has been incorporated with a capital of \$3,000,000, to manufacture cement, lime and affiliated products. The incorporators are R. C. Lubien, St. Angar, Ia.; and Ralph A. Law, Mason City, Ia.

THE CLENSOL CHEMICAL CO., INC., Salem, N. J., has been incorporated with a capital of \$100,000, to manufacture chemicals and chemical byproducts. The incorporators are I. Castelli, Louis O. Bergh and E. E. Cushing, Salem.

THE CALABRA CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemical products. The company is headed by Abraham M. Berman and Harry Chaimken, 8 Crawford St., Roxbury, Mass.

THE MUNN LABORATORIES, 518 Main St., East Orange, N. J., has filed notice of organization to manufacture chemical products. The company is headed by Robert Loder, 60 Walnut St., East Orange.

THE ONTARIO-CORONA OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$5,000,000 to manufacture petroleum products. The incorporators are F. A. Welshans, Alhambra, Cal.; L. R. Kennedy and C. E. White, Ontario, Cal.; and P. W. Lacy, Los Angeles.

THE VICTOR INK CO., Jersey City, N. J., has been incorporated with a capital of \$350,000, to manufacture inks. The incorporators are E. Burke Tinnerty, G. M. Jones and Isador Halprin, Jersey City.

THE DOOLEY MFG. CO., Philmont (Columbia Co.), N. Y., has been incorporated with a capital of \$50,000, to manufacture glue, chemical products, etc. The incorporators are J. E. Clune, E. L. and C. E. Dooley, Philmont.

THE R. R. GLASS WORKS, INC., Providence, R. I., has been incorporated with a capital of \$50,000, to manufacture glass products. The incorporators are Hiram G. Hall, 372 Benefit St.; Peter Perrotta and Ralph Kakusian.

THE PLANTERS' LIME, PHOSPHATE & FERTILIZER CO., Penters Bluff, Ark., has been incorporated with a capital of \$1,500,000, to manufacture fertilizers, lime and affiliated products. The incorporators are J. R. Alexander, Scotts, Ark.; R. R. Ramey, Kensett, Ark.; and J. W. Williamson, Batesville, Ark.

THE ALL-KLEAN MFG. CO., New York, has been incorporated with a capital of \$10,000, to manufacture valve grinding compounds, chemical specialties, etc. The incorporators are C. and C. Cunningham, Jr., and R. Lee, 111 Young St., Brooklyn.

THE TUDOR PRODUCTS CO., New York, has been incorporated with a capital of \$55,000, to manufacture chemicals and chemical byproducts. The incorporators are E. Levy, J. J. Fischer and R. E. Tinsley, 299 Bway.

THE ELK HILLS CRUDE OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$350,000, to manufacture petroleum products. The incorporators are William O. Maxwell, Fred V. Gordon and R. E. Kline, all of Los Angeles. Andrews Toland & Andrews, 916-24 Union Oil Bldg., head the company.

THE CLIMAX SPECIALTIES CO., Jersey City, N. J., has been incorporated with a capital of \$25,000, to manufacture chemicals and chemical byproducts. The incorporators are W. B. Madden, Fred Bebbler and Samuel H. Neve, 1035 Summit Ave.

THE AJAX RUBBER CO., Dallas, Tex., has been incorporated with a capital of \$25,000, to manufacture rubber products. The incorporators are L. D. Ormsby, F. C. Burnett and W. J. Jackson, Dallas.

THE GENESSEE POTTERY CO., Chittenango (Madison Co.), N. Y., has been incorporated with a capital of \$5,000, to manufacture pottery and other ceramic products. The incorporators are A. W. Surles, J. H. Thompson and J. M. Moir, Marcellus, N. Y.

THE DIRECT RUBBER CO., 46 Paterson St., New Brunswick, N. J., has been incorporated with a capital of \$500,000, to manufacture rubber goods. The incorporators are Samuel C. Clark, Willett S. Chinery and John J. Moriarty, New Brunswick.

THE KENNEBEC PULPWOOD CO., Augusta Me., has been incorporated with a capital of \$100,000, to manufacture pulpwood and paper products. Blaine S. Viles is president and W. R. Pattangall treasurer.

THE APEX OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000, to manufacture petroleum products. The incorporators are Arthur C. Gage, Leslie C. Monks and M. L. Jenks, Los Angeles. Adams, Adams & Binford, 716 Van Nuys Bldg., represent the company.

THE BOYSTON PAPER CO., Boston, Mass., has been incorporated with a capital of \$500,000, to manufacture paper products. The incorporators are T. Mercer Atkinson, M. MacGill, Cambridge, Mass.; and Ralph F. Alvord, Auburndale, Mass.

THE HUDSON VALLEY OIL CO., Kingston, N. Y., has been incorporated with a capital of \$30,000, to manufacture petroleum products. The incorporators are C. Wilson, A. R. Newcomb and W. G. Maus, Kingston.

THE NORTHERN REFRACTORIES CO., Ridgway, Pa., has been organized to manufacture firebrick, furnace linings and other refractory products. The company is headed by Ives J. Harvey, Bellefonte, Pa.; M. P. Shanley, Ridgway; and E. J. Burke, Rochester, N. Y.

Capital Increases, Etc.

THE ROESCH ENAMEL RANGE CO., Belleville, Ill., has filed notice of increase in capital from \$15,000 to \$75,000.

THE FALL CITIES HYDRAULIC BRICK CO., Jeffersonville, Ind., has filed notice of increase in capital from \$50,000 to \$100,000.

THE ACME SANITARY POTTERY CO., May St., Trenton, N. J., manufacturer of sanitary earthenware, has filed notice of increase in capital from \$50,000 to \$200,000.

THE ESCANABA PAPER CO., Escanaba, Mich., has filed notice of increase in capital from \$2,800,000 to \$3,000,000.

THE LOCKWAY, STOUCK PAPER CO., Benton Harbor, Mich., has filed notice of increase in capital from \$50,000 to \$100,000.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters will be at the Hotel Rochester.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon April 26 at Rochester, N. Y., for luncheon.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP & PAPER INDUSTRY will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, N. Y., April 11 to 14.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Number 14

Consolidation of Research

By Electro Carbon Group

THE Union Carbide & Carbon Corporation is consolidating its principal research laboratories into a single organization in Long Island City. For this purpose it has leased for a minimum period of five years the entire second floor of a great building, covering a ground area 200 x 600 ft.; the net space available for laboratory activities will be in excess of 100,000 sq.ft.

The principal research laboratories which it is intended to consolidate at the present time are those of the Union Carbide Co. and the Electro Metallurgical Co. at Niagara Falls; the Cleveland and Fremont laboratories of the National Carbon Co., and certain of the laboratory activities of the Linde Air Products Co. at Buffalo, the Prest-O-Lite Company at Indianapolis and the American Ever Ready Works at Long Island City. Only such activities will be transferred as can advantageously be carried on at a point remote from the several factories, and include chemical, electrical, mechanical and physical research. Professional and social organizations of men of science in New York may well congratulate themselves on the advent of the distinguished men of research who will continue their labors as members of the staff of this metropolitan institution.

We have heard complaints of late in regard to over-consolidation of research, but these scarcely apply in the present instance. The corporation has a great purpose in mind; it has on its staff a considerable number of men of signal ability in research, and it is believed that, in bringing together these many minds as to the solution of more pressing problems, earlier and better results not only may be but will be attained. Instead of overspecializing, as is occasionally the case when research is centralized, it is believed that the same men will have the advantage of familiarity with a greater variety of problems, and that a far greater opportunity for convenient consultation, interchange of ideas and team work will be afforded.

The moving force back of this consolidation of research activities is of course the conviction in the minds of the officers that thereby even more rapid progress may be made along those industrial and scientific lines for which the corporation stands. These comprise such varied subjects as the application of the electric furnace to the manufacture of carbide of calcium and other carbides and to the preparation of a wide variety of metals, alloys, refractories, etc.; the manufacture of carbon electrodes for electric furnaces, arc lights, projectors, welding equipment and the like; the production, storage, distribution and utilization of acetylene; the application of acetylene to the welding and cutting of metals and other purposes, and the manufacture of welding and cutting equipment; the

manufacture of carbon and metal-carbon brushes for electric generators and motors and of miscellaneous carbon articles for a wide variety of purposes; the manufacture of storage batteries, of dry cells and of flashlight apparatus and batteries; the liquefaction and fractionation of gas mixtures; the industrial utilization of oxygen; the production of synthetic organic chemicals from acetylene and other hydrocarbons. A mere catalog of the manufactured products would form a small volume, and with the assembling of the majority of the research men from the several plant laboratories it is confidently expected that each will find a wider horizon for his thought and for the application of his work, and that thereby the organization will become a more effective tool for the advancement both of industry and of science.

The new laboratory will have a fascination due to the variety of its problems, and a further interest due to the inherent industrial and scientific significance of its activities. Consider, for example, the single instance of the industrial application of carbon for purposes other than fuel. It is confidently believed that carbon in its multifarious forms has a great and growing future as an industrial raw material, though many such uses have already been widely developed. For example, carbon enters into electrodes for every purpose of heating or illumination; it is a primary component of the familiar dry cell and flashlight battery; it is molded into motor and dynamo brushes; in the form of lampblack it enters largely into such diverse industries as the manufacture of automobile tires and printing inks; in its so-called "activated" form it is a gas mask absorbent, a sugar decolorizer, a collecting agent for gasoline and other condensable vapors, and a powerful catalyst for chemical reactions; in the form of graphite it enters largely into the field of lubrication and is the cornerstone of the electrolytic alkali industry.

In these and many other applications carbon remains in those familiar physical forms which we identify with the name. When we extend our consideration to the chemical aspects we open the door wide into the field of organic chemistry—"the chemistry of the carbon compounds." As to this we cannot do better than to repeat Dr. WHITNEY'S fine statement from his recent Perkin Medal address.

Referring to the great development of coal tar chemistry he said: "New fields are greater in number because the territory of chemical knowledge is so greatly broadened, and new tools are so numerous. The results will depend solely on mentality—not tar. Is it not within reason that another field as great as dyes will be developed directly from carbon itself? The entering gates of organic chemistry reached by the shortest road were apparently opened when calcium carbide was first made. Thus starting with two of our

most abundant mineral products, coal and limestone, and adding water alone, we are supplied with the endothermic gas, acetylene. From this point almost anything seems possible. When we realize that the manufacture of acetone, alcohol, etc., has thus been made possible, from the inorganic raw materials, we might as well expect, by the same road, useful food as certainly as medicaments."

Wanted—

A Nitrogen Industry

WITH fertilizers, explosives, dyestuffs and other chemical products demanding nitrates, ammonia and many other nitrogen compounds, America cannot get along without a nitrogen industry. In this respect every chemist and every chemical establishment can join the Chief of Ordnance in his urgent demand that some provision be made for the stimulation of nitrogen fixation in the United States.

The main question which has been debated during the past year with respect to the nitrogen industry has been whether it should be a Government industry or a matter of private development and control. But that question is now beside the point, because Congress has defeated not only the legislation intended to provide for a nitrogen corporation but also the power development at the Wilson Dam, Muscle Shoals, Ala. However, with the defeat of that legislation the whole question is not closed. There remains the important matter of determining the status and future development of the Government research on various nitrogen-fixing processes. This is at the present stage almost as important a matter as the plant development itself, for today the success of plant operation either private or public will depend more upon well-planned successful research than upon the appropriation of the requisite millions or the satisfaction of political requirements.

The Fixed Nitrogen Research Laboratory at American University has already contributed materially to our knowledge of this basic chemical industry. Approximately a dozen important published contributions from the laboratory staff are on record to demonstrate the important advancement of science in the nitrogen industry which can be expected from this organization. In addition there are more than sixty confidential reports not yet released bearing upon various phases of this question, and in due time and under proper conditions they will become general property for the development of all branches of industry affected. The means to this end are worthy of immediate consideration.

The emergency funds allotted by President WILSON to nitrogen-fixation investigations are still available in adequate amount for the continuation of the fixed nitrogen laboratory for a year or perhaps two years in the future. This laboratory organization is a going concern, working effectively and efficiently on many of the basic problems which can be solved nowhere else as quickly and as cheaply. The question is, Are we to stand by and allow this organization to be disrupted or disbanded altogether? On the part of the chemical industry it would seem that the answer should be emphatically "No."

Some might say that this laboratory organization should be transferred to private hands by allowing the staff to resign and take up employment elsewhere as

private industry saw fit to employ the personnel. A similar suggestion might follow as a natural corollary that the equipment of the laboratory should be sold or placed "in reserve for use in case of emergency," that familiar phrase which means "allowed to rust itself to pieces." On the other hand, a far more sensible plan will be to continue the work of this laboratory on a basis comparable with the work of the Bureau of Chemistry in the food and drug business, the Bureau of Mines in the fields of mining engineering and metallurgy, and the Bureau of Standards in the field of physical science and technology. Not to continue it for the period for which funds are available would be the grossest waste. And such waste at a time like the present is even more unjustifiable than usual.

The Chief of Ordnance has received a recommendation from the director of this laboratory urging the continuance of the work for industrial, agricultural and military purposes, and it seems certain that he must concur therein. If so it then becomes in turn the responsibility of the Secretary of War and the President to approve or amend this program. To these responsible officers and officials the chemical industry can well express its opinion on three matters: (1) Keep this laboratory as a going concern working upon the proper basis for the service of the industry, private and public alike. (2) Decide the matter favorably at once so that the organization can be insured a sufficient permanence to prevent early resignation of the important, and almost irreplaceable, members of the staff. (3) In view of the congressional decision not to advance the nitrogen industry as a publicly owned affair, make available by publication at the earliest proper date all of the results of this important laboratory organization so that the explosives, the dyestuff and the agricultural industries may at the earliest possible time take advantage of them for the general public welfare.

If these three things are done the Government will have contributed materially to the advancement of an adequate nitrogen industry, an industry in which it is as much interested as anyone else can possibly be.

Metallurgy and Civilization

MAN'S progress—the history of civilization—is vitally influenced and even given great impetus at many times by improvements in metallurgy. Still the most ardent enthusiast would not wish to infer that the advancement of our material well-being has been due solely to the efforts of metal workers, for doubtless all living men have had their own influence. But like all other branches of knowledge, metallurgy has been advancing at a rapidly increasing rate; compared to the two thousand years which elapsed between the invention of a bellows for blowing a forge and its equipment with a simple flap valve, announcements of successive discoveries today are made at a perfectly startling rate.

In view of this history of metallurgy, a history of peculiar dignity, the individual now engaged in the art may often wonder what part he may have in its future development. What can one man do with rather limited experimental equipment? The most-talked-of researches now are the co-operative researches planned on a large scale and requiring the labor of many investigators, or the systematic investigations supported by our large manufacturing concerns.

One may fairly point out, however, that research cannot be planned, any more than an expedition can be outfitted to locate a new gold lode. A true discoverer sets sail boldly into the unknown; his followers, traveling in companies, are mere map-makers; collectors of needed and precise information, truly, but of value to further research mostly as a new expeditionary base.

Again, is it not most curious that fundamental discoveries are made with absurdly meager equipment, not at all in keeping with the magnitude of the subject? The CURIES did not need to finger an electron to discover radioactivity—indeed no man or woman ever will. Nor did NEWTON weigh a planet before announcing the law of gravitation—in fact it is rumored that all he needed was to see an apple fall. FARADAY discovered electric induction—the foundation principle of all we know as electrical engineering today—with a magnet and a loop of wire. More recently, BENEDICKS proved the highly controversial and baffling question of thermo-electric currents in a homogeneous metal by merely cutting a wire in the center and crossing the ends.

Metallurgists may thus well derive inspiration and courage in reflecting on the important work which is possible even with a moderate amount of instrumental equipment, when reinforced with a large amount of intellectual resource.

German Chemists in American Employ

APPARENTLY the emigration to the United States of a few German dye chemists has created more disturbance in the Vaterland than in this country, and official steps are being taken to discourage further exodus of German scientists and technologists. It is reported that one of the Bayer chemists was under detention at Rotterdam on demand of the German Government on a charge of theft of documents containing technical and commercial information. Incidentally a lot of noisy talk has emanated from the German side to the effect that the emigrants violated terms of an agreement under which they were employed and that they brought with them to the United States trunks and other receptacles full of voluminous manuscripts and data representing the innermost secrets of German dye establishments. It is also alleged in German quarters that the du Pont company cunningly enticed the Germans to forsake their country and default in their agreements with employers. Personal information from Berlin, however, reassures us on these points, and advises us that no great inducement or artfulness is necessary to attract Germans into American service. In fact, our correspondent says that numerous German engineers would gladly respond to offers of foreign employment. As for the imputation of a breach of contract on the part of the chemists who have already come to the United States, we are advised that the German law does not recognize as binding contracts which bar employees from accepting positions in competing establishments. However all this may be, we have previously expressed our attitude on the question and refer to it again merely to affirm our belief that American manufacturers can be trusted to use good judgment in any decision to obtain the technical services of Germans and others who can furnish information that will advance our industries. Voluntary employment of German brains may prove more acceptable than forced purchase of German dyes.

U. S. Steel Corporation Twenty Years Old

IN SOME industries twenty years is not a long time. In the steel industry it is a very long time. Two decades ago the steel industry was a full-fledged industry. Three decades ago steel was just coming into its own. Long previously it had supplanted wrought iron in rails, but only then was it becoming the dominant material for other rolled products in general.

It is an event that at the end of last month the United States Steel Corporation completed its twentieth year, for it was on April 1, 1901, that the Steel Corporation came into business existence, a consolidation of two concerns, the Carnegie Steel Company and the Federal Steel Company.

Interesting as is the history of the steel industry as an industry in the past twenty years, the history of the United States Steel Corporation as an institution is much more interesting in its relations to society. The corporation as formed was what was known in the parlance of that day as "a trust," a term that cared not for details and simply connoted monopoly or a desire to monopolize. Now "trusts" had been interdicted by the Sherman law, an act of a little less than a thousand words, dated July 2, 1890, but the Supreme Court decision of 1894 in the Knight "sugar trust" case seemed to remove actual consolidations of property from the scope of the act. The view of the man in the street twenty years ago was that trusts were wrong, but certain descriptions of "trusts" the public would have to put up with.

The friends of the Steel Corporation insisted that no "trust" was contemplated. They wished to avoid "cut-throat competition" and the unnecessary duplication of plants, introduce economies in manufacture and build up a sound export trade, to replace the "dumping" process that had sometimes been indulged in.

Whatever were the motives and aspirations, the interesting and important thing today is that the United States Steel Corporation has "made good" on all points. One reason is ex-Judge ELBERT H. GARY. Many men might have done what he has done, though that is very doubtful. The fact is that this man, chairman for twenty long, eventful and exciting years in steel, has done the work. He has had very good advisers, but so have other men, who failed. His chief characteristic is balance, poise. He cannot be stampeded. He never "gets rattled," whether as in 1920 the "independents" advance their prices far above the prices he thinks should be charged or, as in the past two months, when they cut his prices.

The corporation is strong and stable today, sound and safe. Yet it is by no means a monopoly or partial monopoly as at first it was expected to be, for it has only about 43 per cent of the steel ingot-producing capacity of the country. When it became clear that it was not and would not approach monopoly in point of percentage of capacity the corporation was charged by those who feared for results with being a "dominant interest" or a "leader." That the corporation is not such now is shown by the fact that it neither held the prices of independent steel producers down in 1920 nor held them up in recent months.

The United States Steel Corporation has "made good" to its stockholders, its employees and the public by being merely a great manufacturing organization, very wisely and safely managed.

Comparison of Various Methods of Water Purification

To the Editor of Chemical & Metallurgical Engineering

SIR:—Mr. Taylor's article on this subject in the Jan. 19 number of CHEMICAL & METALLURGICAL ENGINEERING very correctly and clearly describes the chemistry involved and relative advantages of the zeolite water softener as compared with the cold process lime-and-soda water softener, but is incomplete for the reason that it makes no reference to the hot process lime-and-soda water softener.

This omission is particularly noticeable for the reason that much of his article pertains to softening water for boiler feed purposes, whereas the hot process water softener has been developed primarily to meet the need of a hot soft water for boilers. Its development has been based on the fact that it is economical and otherwise advantageous to heat boiler feed water to approximately 210 deg. F. before feeding to the boilers and the well-known fact that heat generally aids chemical reactions, particularly those involved in softening water with lime and soda ash.

The accompanying curves show the value of heat in softening water. The practical value of heat in softening water is also well illustrated by the following analyses representing Delaware River water before and after treatment in a Sorge-Cochrane hot process water softener at a large chemical manufacturing plant near Philadelphia.

	Grains per U. S. Gal. Before Treatment	Grains per U. S. Gal. After Treatment
Calcium carbonate.....	0.70	1.23
Calcium sulphate.....	1.40	
Magnesium carbonate.....	.64	.18
Silica	.35	.35
Iron oxide and alumina	.06	...
Sodium sulphate.....	2.39	2.62
Sodium chloride.....	.766	1.28
Sodium carbonate.....		2.04
Volatile and organic.....	.58	.58
Total solids by evaporation.....	6.88	8.17
Suspended matter	5.01	none

You will observe the sum of the calcium and magnesium carbonates in the Delaware River water treated by the hot process softener is only 1.41 grains per gallon, as compared with 2.99 grains per gallon reported by Mr. Taylor as being representative of the best results to be obtained by the cold process lime-and-soda treatment. Furthermore, the excess sodium carbonate, 2.04 grains per gallon, is slightly less than the excess sodium carbonate which he reported, 2.33 grains per gallon; the significance of the excess sodium carbonate being that the greater the excess chemical fed the lower is it possible to reduce the calcium and magnesium salts. By feeding 3 to 4 grains per gallon excess sodium carbonate with the hot process lime-and-soda treatment the calcium and magnesium carbonates are reduced to approximately $\frac{1}{2}$ grain per gallon. Again, the calcium and magnesium carbonate in the treated water, as above reported, is only very slightly greater than that reported by Mr. Taylor as being most representative of waters treated by zeolite softeners, his analysis showing

a total of 1.13 grains per gallon. His analysis also shows an excess of 17.44 grains per gallon sodium carbonate, which he correctly stated as being highly objectionable for boiler feed.

The analysis of treated water above given by no means represents exceptional treatment, for it is representative of a large number of analyses called to my attention of samples of water treated by the hot process lime-and-soda softener.

The small amount of calcium and magnesium salts remaining in solution after the hot process treatment, for a correspondingly small excess sodium carbonate, makes this method of water treatment highly desirable for boiler feed, which in addition to being soft should also be hot.

Mr. Taylor's article also refers to boiler compounds generally being more satisfactory than water softeners

CURVE SHOWING THE VALUE OF HEAT IN SOFTENING WATER

Solid curves show calcium carbonate remaining in solution after treating calcium sulphate with sodium carbonate (soda ash). Dotted curves show magnesium hydrate remaining in solution after treating magnesium sulphate with calcium hydrate (lime). In all tests the theoretical quantity of softening chemicals was used to combine with the scale-forming solids.

for water-tubular boilers. This statement is not in accord with present-day experience, when water-tubular boilers are generally overloaded, particularly on peak loads. Many boilers fed with waters having less than 8 grains per gallon of encrusting solids (suggested by Mr. Taylor as the minimum hardness requiring water softeners) have developed very serious troubles with scale and priming since carrying high overloads, whereas before operating the boiler at overload apparently satisfactory results had been obtained by the use of boiler compounds.

The chemical plant above referred to, of which water analyses are given before and after treatment, is one such. For many years this plant had been operated without serious tube troubles, but when forcing the boilers, as became possible when installing oil burners, very serious tube troubles resulted, which were corrected by the installation of a hot process water softener for treatment of the boiler feed.

While a satisfactory theoretical explanation may not easily be given for the cause of priming and foaming of boilers, it is well established that large amounts of suspended solids as well as high concentration of sodium

salts within the boiler will cause priming and the more common cause for foaming is suspended matter. It is therefore obviously advantageous to give the boiler feed such treatment as to reduce to the minimum solids to be suspended in the boiler and at the same time keep the concentration of sodium salts as low as possible. This demands that the solids originally suspended in the water be completely removed and that, further, those solids made insoluble by boiler evaporation, as calcium and magnesium salts, should be reduced to the minimum while feeding the smallest permissible excess sodium carbonate. The analysis of treated water above reported is a good representation of what may be expected in this regard if the water is given a hot process lime-and-soda treatment.

If it is desired to feed some anti-foaming compound, this may equally as well be done after the water is softened as before, although experience generally shows that where the water is properly softened anti-foaming compounds can give no further improvement and are accordingly not required.

Porcelain Enameling Furnaces

To the Editor of Chemical & Metallurgical Engineering

SIR:—In the interesting paper on "Porcelain Enameling Furnaces" by C. G. Armstrong published in your issue of March 16 the author says:

"The electric furnace has not entered the commercial field as yet, *due to great heat losses entailed.*" The italics are mine.

Now unless the design of an electric furnace of this kind is very bad it is impossible that its failure should be "due to great heat losses entailed," because one of the great advantages of electric heating in such a furnace is the possibility of reducing heat losses to a minimum. On the other hand, in the fuel-fired furnace heat losses are bound to be high, particularly if no recuperative device is employed.

Several years ago at the FitzGerald Laboratories experiments were made on a furnace used both for baking porcelain and also glazing biscuit ware. The longest continuous run of the furnace lasted fifty-four days and during that time experiments were tried at various temperatures from 1,000 to 1,500 deg. C. (about 1,800 to 2,700 deg. F.). The results were very satisfactory and the indications at that time were that electric energy could be used with such high efficiency that even though the cost of electrically-generated heat was much higher than fuel-generated heat, yet because of the more efficient way in which the former could be used it would actually be more economical. With the relatively great increase in the cost of fuel-generated heat which we now have it is probable that electrically-heated porcelain and enameling furnaces would compete successfully with fuel-fired furnaces in localities where reasonably low-priced electric energy is available.

The only real difficulty in the way of the electric furnace for this purpose is the discovery of some one with sufficient courage to spend the money necessary for development. The preliminary work has been done already so that we now know how such a furnace should be designed; but to go further it is necessary to construct a commercial apparatus.

Library and Research Work

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of March 2 is a communication from "Librarian" in which attention is called to an article in the editorial section of the *New York Times* entitled "Engineers Join in Research Work." He further suggests in this connection a "library link" that might serve in two ways; first, by the publishing of a weekly index of abstracts of articles in current technical papers and second, in "the founding of a large central card catalog of all technical books, pamphlets, trade catalogs, translations, carefully analyzed for every article of value in them."

He also calls to mind some of the large technical libraries of this country and mentions that "this proposed library has its prototype in the International Institute of Bibliography at Brussels, which fortunately escaped the ruthlessness of the Germans and recently filed its twelve-millionth card. The fact that the International Institute of Bibliography has existed even through war-ridden days of Belgium long enough to file its twelve-millionth card is indicative of the commercial possibilities of a similar scheme in this country where the machinery for its accomplishment is greater."

In this connection it would be interesting to inquire whether "Librarian" knows to what extent practical use is made of the twelve million cards of the International Institute. Are distance and time a barrier to the use of this index outside of the city of Brussels? How much is it used by means of communication through the mail and do people actually make journeys to Brussels to use it? How much is it used by the residents of Brussels? Do those who actually use it find it difficult to find the few references wanted in a catalog of twelve million cards? In other words, does its great size defeat the purpose for which this elaborate card index system was devised?

If such a large catalog is of value to those who happen to be in its vicinity, would it not be worth while to incur the somewhat larger expense of printing and making it available to all corners of the earth? In comparing these two methods it is perhaps not unfair to say that the card catalog should be compared to a reservoir of static information and that the printed catalog available at moderate cost anywhere might be compared to a central power station with lines of distribution.

New York City.

H. W. WILSON.

Who Is a Chemist?

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with the discussions which have appeared recently in your columns as to what constitutes a chemist I am inclosing the following want advertisement clipped from the *New York Herald* of March 13:

CHEMIST FOR LABORATORY; NO SPECIAL EXPERIENCE NECESSARY, BUT MUST PROVE TO BE ABSOLUTELY RELIABLE, CONSCIENTIOUS AND OF GOOD CHARACTER; ONLY APPLICATIONS GIVING DETAILED INFORMATION AND SUPPLYING BUSINESS AND FAMILY REFERENCES WILL BE CONSIDERED. Y 752 HERALD, HERALD SQ.

Their description of "chemist for laboratory; no special experience necessary" is another example of the altogether too prevalent conception of the chemical profession.

What these people apparently want, without knowing it, is probably a beaker boy who can "do" chemistry on the side.

CHEMICALLY TRAINED WORKER.

Massena, N. Y.

British Chemical Industry

(FROM OUR LONDON CORRESPONDENT)

LONDON, March 14, 1921.

THE political situation is expected to benefit chemical markets materially. Before the breakdown of the negotiations of the London Conference a little improvement was noticeable, though buying was still on a hand-to-mouth basis. In the heavy chemical trade prices have been well maintained in spite of foreign competition and in some cases makers have announced their intention of closing down rather than sell at unremunerative prices.

STAGNATION IN GERMAN IMPORTS EXPECTED

The proposal to make importers pay half of the value of German goods to the British Treasury is likely to stifle the influx of German chemicals for some time and to give a much needed breathing spell to manufacturers. Grave doubts are expressed as to the effectiveness of the measures to be adopted, particularly in regard to payments made by bills of exchange and in regard to the liability of importers under running contracts for goods sold forward in this country. Apparently goods for re-exportation will be exempted, and this may prove a welcome, if temporary, loophole in addition to that provided by shipment to or through neutral countries. Meanwhile there remains the possibility of German producers refusing to supply at all under the conditions to be imposed or of demanding deposits or enhanced prices. On the other hand, it is considered that the expected reduction of German imports of chemicals will be of immediate benefit to American producers, and considerable business is stated to have passed already in anticipation of rising prices for certain commodities. The fertilizer trade is better, particularly as regards nitrate of soda and sulphate of ammonia and increased activity is expected. Basic slag is an exception, particularly as regards export, trade with Australia being almost impossible on account of credit restrictions in that country.

TRADERS DEMAND SECRECY IN REGARD TO PURCHASERS

The arbitrary attitude of certain manufacturers in refusing supplies to merchants (see previous article in *CHEM. & MET.*, March 9, p. 418) for markets in which the manufacturers have their own agent has, it is understood, been definitely challenged in one specific case, where refusal led to the order being placed abroad. The matter has apparently been referred to the Board of Trade, but it is likely that the cause of friction will be removed without action by the government. In this connection it is interesting to note that a conditional promise has been given that the advisory committee on dyestuffs appointed by the Board of Trade will not be given the names of purchasers of dyestuffs imported under license except in special circumstances, the information remaining normally in the confidential hands of the Secretariat. The constitution of the advisory committee is now known and the promise given was obviously necessary on account of the consumers' and manufacturers' representatives. Dr. M. O. Forster and W. J. U. Woolcock, M. P., were obvious selections for this committee and E. V. Evans, chief chemist of the South Metropolitan Gas Co. is also of the number, being officially and perhaps with unconscious humor described as the "treasurer of the Society of Chemical Industry." The names of the members of the develop-

ment committee to be set up under the dyestuffs restriction act have not yet been announced.

The key industries bill, under which it was hoped that the fine chemical industry would receive a measure of protection similar to that given under the dyestuffs act, will not be introduced until after Easter, owing to pressure of political and financial business in the houses of Parliament. It is understood that the bill will be very hotly contested and it is by no means unlikely that it will fail to be carried into effect, at any rate on the comprehensive scale originally proposed. Official support, while outwardly enthusiastic, is actually believed to be very lukewarm and the propaganda and press campaign in connection with the fine chemical industry seems to have been overdone.

MR. KESTNER READS IMPORTANT PAPER BEFORE THE SOCIETY OF CHEMICAL INDUSTRY

Mr. Kestner's paper last week on the "Degassing and Purification of Boiler Feed Water" at the Institution of Mechanical Engineers attracted considerable attention and set a very welcome precedent for future joint meetings between chemists and engineers; it also tends to show that the society is increasingly appreciating its responsibility in the furtherance of chemical engineering knowledge. The paper dealt in detail with the process of continuous blowing down used in conjunction with hot purification, whereby a thermal saving is effected and the gases dissolved in the feed water are eliminated. Agitation and heat increase the speed of reaction and the settlement of the precipitate and the apparatus proposed consists of a steam separator, a central reservoir and heater, a re-heater and a precipitation chamber, soda being used as the reagent. The discussion brought out the fact that other workers have been proceeding on similar lines in the past, but the paper and discussion will do much to clarify the knowledge at present available on this important subject.

Details have now been given of the annual meeting of the society to be held in Canada at the end of August. The trip is likely to prove sufficiently expensive to prevent a large and representative attendance, though it is hoped that the larger firms will, as a matter of policy, defray the expenses of special representatives, particularly as an extension of the tour to New York will enable them to visit the National Exposition of Chemical Industries. It is felt that a larger attendance at what is, after all, a function of international importance could be secured by arrangements for cheaper travel and accommodation and no doubt the proverbial hospitality of America will solve the difficulty for the one hundred-odd delegates who are expected to make the trip.

PERSONAL NOTES

In Lord Moulton British chemical industry has lost a personality and a leader whose place it will be extraordinarily difficult to fill. Those who were associated with him during the war learned to appreciate not only his legal and mathematical ability, but also his uncanny aptitude for sizing up an individual correctly and placing him in his proper niche in a harmonious whole. He had hoped to save the fine chemical industry as well as that of dyestuffs, and the propaganda campaign in regard to the former will suffer from the loss of his leadership at a critical time unless another man can be found to take his place. Other losses to science have been occasioned by the deaths of Prof. Odling, F.R.S., and Prof. Miall, F.R.S.

GENERAL VIEW FIXED NITROGEN RESEARCH LABORATORY

Government Fixed Nitrogen Research

The Present Status and Recommendations for the Future of the Investigations of the Fixed Nitrogen Research Laboratory, American University, Washington, D. C., as Reported to the Chief of the Nitrate Division by the Directors of the Laboratory, March 15, 1921

BY R. C. TOLMAN

IN ORDER that a wise decision may be made as to the future of the Fixed Nitrogen Research Laboratory, the following brief statement as to its present activities and tentative future plans is made:

The Fixed Nitrogen Research Laboratory was founded by an order of the Secretary of War dated March 29, 1919, and has been operated, with a budget of \$300,000 a year, from funds which were made available to the President of the United States by the national defense act of June 3, 1916, specifically authorizing him to "cause to be made such investigations as in his judgment are necessary to determine the best, cheapest and most available means for the production of nitrates and other products for munitions of war and useful in the manufacture of fertilizers and other useful products, by water power or any other power, as in his judgment is the best and cheapest to use." The laboratory is engaged in carrying out these provisions of this act, and there are still funds available from the original appropriation which will make it possible to continue the work for two years longer, provided such continuation seems wise to the Secretary of War and the President of the United States.

PERSONNEL CAREFULLY SELECTED

The laboratory is located at the American University, Washington, D. C., making use of buildings and equipment formerly used by the Research Division of the Chemical Warfare Service. It has a total personnel of between 110 and 120 persons, 50 of whom are chemists. This personnel has been very carefully selected for the work in hand, many of the men having had experience along similar lines in the Research Division, Chemical Warfare Service. The total equipment of the laboratory for purposes of chemical researches has a value of approximately \$399,000, much of which has been specially designed and constructed for the

difficult researches in progress. The largest building in use by the laboratory is loaned by the American University and a duplication of the entire plant is roughly estimated to cost in the neighborhood of a million dollars.

THE ACTIVITIES OF THE LABORATORY

The main work of the laboratory has been to study the fixation of nitrogen by the cyanamide process, by the Haber process and by the arc process, and to study the methods of transforming the various forms of nitrogen-containing products so as to make them most available for military, agricultural or industrial uses.

The work of the laboratory has been carried out with particular reference to the changes in equipment and methods of operation that would be necessary in order that the Muscle Shoals (cyanamide) plant might be operated in peacetime to produce fertilizer material instead of explosives, and with reference to the changes that must be made in the smaller Sheffield (Haber) plant in order to make its operation successful.

The results of these investigations have been presented to the Chief of the Nitrate Division in a series of sixty-one confidential reports.

Summaries of the results of this work will be found in the Reports of the Director, Aug. 20, 1920, and Jan. 20, 1921. These reports have been held confidential in order that the material contained therein should be available to the Government, in case Congress should decide to operate the two existing nitrate plants as a governmental activity. It is the plan of the laboratory, however, to publish a large portion of this material for the general use of the nitrogen industry in case Congress should decide that the serious national problem of nitrogen fixation can safely be left to development by private capital.

Besides the confidential reports which the laboratory has made to the Chief of the Nitrate Division, the laboratory has also published in the *Journal* of the American Chemical Society and elsewhere ten purely scientific articles.¹

The laboratory plans in the future to publish a very considerable number of further purely scientific articles, and also to publish such technical material now contained in the confidential reports as will be of general advantage to the nitrogen industry without jeopardizing the special interests of the Government.

THE FUTURE POLICY OF THE LABORATORY

Owing to the potential seriousness of the nitrogen problem from a national point of view, it is the belief of the writer that the Fixed Nitrogen Research Laboratory should be continued on its present basis, in order that the specially trained personnel of the laboratory and its special equipment for experimental work may be utilized for the maximum public benefit. The question as to whether the Muscle Shoals plant is to be operated by the Government or the development of the nitrogen industry is to be left to private capital has no *direct* bearing on the desirability of continuing the activities of the laboratory. In case the Muscle Shoals and Sheffield plants are operated by the Government, the information collected by the laboratory will be available for the Government, while in case the plants are dismantled, there will be an even greater national need for the kind of information that can be obtained by the laboratory in order that the nitrogen industry may be scientifically developed by private capital.

THE CYANAMIDE AND HABER PROBLEMS

As to the cyanamide problem, it is believed that eight or ten months' more work will be sufficient for rounding out a great portion of the work planned, although a certain amount of attention must always be paid to the cyanamide process, so long as that is the only one by which nitrogen can actually be fixed in America.

The work on cyanamide was originally undertaken at the specific direction of the Fixed Nitrogen Administrator, Arthur Graham Glasgow, because of the Government's ownership of the great Muscle Shoals plant, which will produce 220,000 tons of cyanamide per annum. The main purpose of this work has been to study cyanamide and its various possible transformation products from the point of view of their utility in agriculture, explosives and the arts. The laboratory has already collected an enormous amount of information as to the various compounds which can be

prepared from this material, as will be seen from the reports to the Chief of the Nitrate Division. A large amount of further information is now coming through in the form of additional reports, and a number of important experimental investigations are being brought to a close. The writing up of this material alone will be a task of several months' duration, and all of this material should be made available for the Government in the form of confidential reports if the Muscle Shoals plant is to be operated by the Government, and should be made available to the general public in the form of publications if the Government is not to operate the Muscle Shoals plant.

Although the cyanamide process is one of the best known and best established methods of fixing nitrogen and although the laboratory has completed more work in connection with the cyanamide process than in connection with the other methods of nitrogen fixation, it is not believed that an entire abandonment of the work on the cyanamide process should be contemplated. The cyanamide process is at the present time the only process by which nitrogen can be fixed in America in case of emergency. The Haber process, which under certain industrial conditions can certainly displace the cyanamide process, has never been commercially operated outside of Germany and has very great inherent difficulties connected with handling large quantities of flammable gas at high pressures and high temperatures. This laboratory believes that the cyanamide process will remain an important method of fixing nitrogen for many years to come. It is susceptible of considerable improvement and can furnish a great variety of nitrogen products. In this connection particular attention should be called to the fact that nitroguanidine is almost

MAIN BUILDING OF THE FIXED NITROGEN RESEARCH LABORATORY LOANED BY THE AMERICAN UNIVERSITY, WASHINGTON, D. C.

certain to be an important constituent in new smokeless powders. The Ammunition Division of the Ordnance Department and this laboratory are working on the production of dicyandiamide, guanidine and nitroguanidine from cyanamide. Except for the Muscle Shoals plant, the only source of dicyandiamide, guanidine and the end product nitroguanidine in this hemisphere would be the plant of the American Cyanamid Co. which is located in Canada.

The work of the laboratory on the Haber problem

was undertaken primarily because of the partly developed Sheffield plant which was designed for the Government to operate in accordance with the Haber process. This plant failed to operate successfully because of incorrect engineering design, because a satisfactory catalyst for the synthesis of ammonia had not been developed, and because of the great difficulties connected with the solution of such a complicated process in a limited time under war conditions.

In connection with this problem the laboratory is still in the midst of most important and difficult investigations. We have obtained a catalyst for the reaction between nitrogen and hydrogen to form ammonia which is, we believe, equal if not superior to the catalyst which the Germans had obtained up to the time of the armistice when the Oppau plant was made available for Allied inspection. Our catalyst is satisfactory, both from the point of view of stability and from the point of view of the large yield of ammonia which it gives.

CATALYST-TESTING PLANT. COMPRESSORS

We believe, however, that much superior catalysts can be made, and that the theory of catalytic action can be so elucidated with further work as to put the whole art of catalyst manufacture on a firm scientific basis.

For the purpose of catalyst testing we have developed a high-pressure catalyst-testing plant at a cost of between \$90,000 and \$100,000, which has now been in successful and continuous operation for nearly a year and which is, as far as we know, the only catalyst-testing plant outside of Germany which has ever been operated continuously for more than a week at a time. This plant is operated on a shift basis twenty-four hours per day with a specially trained personnel, and we have only begun to realize on the cost of the investment involved. The testing of catalysts for ammonia synthesis will certainly be an important need of the nitrogen industry in America for many years to come, and the unusual equipment at the Fixed Nitrogen Research Laboratory should certainly be maintained available for testing catalysts whether developed in the future by the Government or by the industries.

For testing catalysts at lower pressures, for studying the theory of catalytic action and for carrying out other chemical researches incidental to the development of the Haber process, we have installed special apparatus at a cost of about \$20,000. The disorganization

of the work being carried on with this apparatus would be a very serious loss to the country.

Among other contributions to the Haber problem, we have started an elaborate set of tests on the ability of different alloy steels to withstand the action of nitrogen, hydrogen and ammonia at high temperatures and pressures. This is a very important problem, since ordinary steel forms nitride of iron under these conditions and bombs constructed from ordinary steel for the catalyst chamber will disintegrate and finally explode. The preliminary work for this test has been carried out in co-operation with the Technical Staff of the Ordnance Department and partly at their expense, and has already cost in the neighborhood of \$16,000 to \$20,000. This money has been expended in the purchase of the twenty-four different kinds of material to be tested, in the construction of the test bombs and test specimens, in carrying out the initial tensile, compression and shearing tests, in making the initial micrographic examination of the steels, and in building the heaters and auxiliary furnaces for carrying the specimens under test. This apparatus is now ready to be assembled and it is planned to maintain the specimens under the conditions of high temperature, pressure and gas concentrations for a period of a year, when the specimens will be removed for their final test and micrographic examination. This work will give most important information in connection with the construction of Haber plants. It will cost us approximately \$10,000 to complete the test if it is run in connection with our catalyst-testing plant, where it can be controlled by our regular operators and where the supply of gas is continuously available. If all the apparatus and specimens already constructed were turned over to be operated independently of our catalyst-testing plant, it might cost from \$40,000 to \$50,000 to complete the work.

THE ARC PROBLEM

As to the arc problem, the laboratory has installed special equipment for this study, having a value of about \$14,000. From a military point of view this is one of the most important methods of nitrogen fixation, since it can be most rapidly installed in case of war and since it provides nitrogen at once in the nitrate form without the necessity of any oxidation from the ammonia form. Since the Government owns no arc plants, we have, for the time being, given less attention to this process than to the others and have confined ourselves to studying the fundamental theory of chemical reactions in the path of the electric discharges. Owing to the great difficulty of the problems involved, we have only begun to realize on the time and investment which we have put into this work. At the present time very important information is coming through as to the maximum yield of ozone which can be obtained by an electric discharge under the most favorable conditions. It is believed that the work on the arc process should be extended and vigorously pushed, since it is by no means out of the question that very fundamental improvements in this process can be achieved.

OTHER METHODS OF NITROGEN FIXATION

Attention must be called to the fact that the laboratory has up to the present time made no serious investigation of other methods of nitrogen fixation than the three mentioned above. The laboratory strongly

believes that various modifications of the cyanide process such as that proposed by Bucher and partially developed at the Government Saltville plant, and such as the Mehner process, which is being developed in Germany, should be given a thorough study. Plans for this work are already under way, and it is believed that the laboratory should divert personnel from the cyanamide section to work on the cyanide process and to prosecute more vigorously the work on the arc process as soon as this becomes possible.

AGRICULTURAL WORK

Special attention should be called to the agricultural work of the laboratory. This has been carried out partly by means of pot and field tests made in co-operation with the Bureau of Plant Industry of the Department of Agriculture, and partly by our own experimental work at the two Alabama plants, where twenty acres was given over to agricultural tests last year. It might seem that the carrying out of such tests was hardly the function of the War Department. The work, however, is a direct consequence of the very peculiar chemical nature of cyanamide which makes its utilization in agriculture a matter that needs further investigation, and the work has been carried out in the closest co-operation with the Department of Agriculture.

The samples of fertilizer material for next year's tests at the plants are now being prepared by the laboratory. It is very important that this work should continue for at least another year, owing to the great variability in the results obtained in field tests. The laboratory has already collected very important information as to the behavior of about ten nitrogen-containing substances in these field tests, but the value of the work will be greatly increased if the conclusions are made more certain by further tests using as far as possible the same fertilizer materials on the same plots. This is customary in ordinary agricultural experiments where the continuation of the tests often runs through a series of years in order to eliminate the variable climatic and other factors.

VITAL IMPORTANCE OF THE NITROGEN FIXATION PROBLEM

The problem of nitrogen fixation is one of vital importance to this country both in war and in peace. The element forms an essential constituent of explosives, of fertilizers, of dyestuffs and many other substances used in the arts. In time of war the necessity of importing Chilean saltpeter, with its attendant uncertainties and tie-up of carrying capacity, is very serious. In time of peace the use of nitrogen in fertilizers is only limited by the supply and, if available, larger quantities would be used for increasing the food and other crops necessary for the country's welfare.

As Prof. Shimer of the Massachusetts Institute of Technology has put it, man has passed through the stone age, the bronze age and the iron age and now is in the nitrogen age. Although nitrogen is one of the most abundant chemical elements, forming four-fifths of the earth's atmosphere, it is one of the most difficult to capture in useful chemical combination. The main function of the Fixed Nitrogen Research Laboratory is to show America how to carry out this capture and how to transform the different nitrogen compounds one into another.

The nitrogen-containing explosives necessary to keep fifty divisions in the field for one year have a value of approximately \$500,000,000. Prof. Jacob G. Lipman estimates that the total loss of nitrogen from the arable land under cultivation in the United States is equivalent to 15,000,000 to 20,000,000 tons of ammonium sulphate per annum, and although it would be impractical at the present time to replace all of this nitrogen, it represents a loss of material worth in the neighborhood of \$1,000,000,000 a year. Surely the expenditure of \$300,000 a year at the Fixed Nitrogen Research Laboratory to keep abreast with the work of other nations on nitrogen fixation is small insurance.

VALUE OF RESEARCH IN NITROGEN FIXATION

Germany spent about ten years in perfecting the Haber process before going into the late war and after she was cut off from the importation of Chilean saltpeter she was still able to continue the war for four years. It is believed that during the last three years of the war she obtained her nitrogen for explosives

CATALYST-TESTING PLANT. REACTION BOMBS

and for food production almost exclusively from the cyanamide and the Haber processes, with perhaps a little importation from Norway of nitrogen fixed by the arc process. This German development meant far more research than is even contemplated at the Fixed Nitrogen Research Laboratory. At the Oppau plant alone there was a research laboratory costing \$1,000,000 and employing 200 research chemists, quite independent of the chemists doing routine work.

BODY OF EXPERTS HERE SECOND TO NONE OUTSIDE OF GERMANY

At the time of our entrance into the war, America had no method of fixing nitrogen within her own borders and had only a few men in the Government service who were even at all familiar with methods of nitrogen fixation. There is now a body of experts at the Fixed Nitrogen Research Laboratory and connected with the Nitrate Division as a whole, whose information concerning nitrogen fixation could hardly be duplicated outside of Germany. If such a body of Government experts had been available at the time of our entrance into the war, it would certainly have been appreciated that the Haber process had not been sufficiently developed in America to warrant the con-

struction of the Sheffield plant, while the construction of the great Muscle Shoals plant, which was built and in operation in less than a year and had already produced 1,700 tons of ammonium nitrate before being shut down, might have been started a year earlier.

ADVANTAGES OF A PERMANENT GOVERNMENT AGENCY TO STUDY NITROGEN FIXATION PROBLEMS

It is our belief that a laboratory for studying the fixation of nitrogen should be a permanent agency of the Government, and that the present laboratory should certainly be continued as long as the funds which Congress wisely appropriated for the specific study of nitrogen fixation are still available.

In this connection it should be specially pointed out that although research on the nitrogen problem has been carried on, particularly in Germany, for many years and will always continue, the work differs from other scientific work in that the results are kept secret to an unusual extent. We can get no reliable information concerning ammonia catalysts, for example, from the German literature. Attention should also be called to the fact that the personnel of the Fixed Nitrogen Research Laboratory are all civilians. If the laboratory is disbanded it will be very difficult to get them together again.

Although the laboratory is working under great disadvantages owing to the present uncertainty as to its future and has already begun to lose personnel because of this uncertainty, it is realized that a wise decision of this question is a very complex matter. This is specially true since it is difficult to obtain any clear picture of the activities of the laboratory without a careful study made at the laboratory itself. Before any decision is made as to the future, it is believed that the work of the laboratory should be studied by some body of technical experts who can estimate the importance of its researches to the Government, to the nitrogen industry and to the country as a whole.

Recovery of the Beet Sugar Industry in France

A forecast by the Ministry of Agriculture indicates that the French beet sugar production from the crop of 1924-25 will probably reach 590,000 metric tons (metric ton = 2,204 lb.), or 68 per cent of its normal pre-war output.

During 1913-14, the last crop year before the war, there were in France 213 mills operating, producing 864,814 metric tons of 100 deg. sugar, at an average of 16.95 per cent extraction, from 6,674,022 tons of beets grown on 566,309 acres of land.

During the war there were destroyed completely 135 sugar mills, located in the ravaged areas of the northern departments. There remained intact seventy-eight mills, but with heavy plant deterioration due to enforced idleness, a deterioration necessitating repairs or replacement of the most expensive equipment, such as slicing machinery, pumping systems, triple and quadruple effects, vacuum pans, crystallizers and centrifugal machines.

In 1918-19, the first crop year after the war, French mills produced 107,841 tons of beet sugar. In 1919-20 the sugar output rose to 152,332 tons from 163,496 acres of beets, at an average extraction of 17.57 per cent of the weight of beets sliced. The average extraction of 100 deg. sugar for ten years prior to 1914 was about 16 per cent. For the present crop of 1920-21 there was

sown in beets 202,230 acres, the average extraction to date is 17.69 per cent and the estimated sugar production will be 350,000 tons at 100 deg. polarization, thus exceeding an earlier estimate of 250,000 tons. The increased sugar extraction, it should be observed, is due to deep plowing of land which had lain fallow for four years, more thorough cultivation, and heavier fertilization with potash now available at reduced cost from the Alsace-Lorraine deposits. The daily slicing capacity of mills now in operation is 2,375 tons of beets, and mills about to resume grinding will have an additional beet capacity of about 3,000 tons per day.

Future sugar production per crop is estimated as follows: 1922-23 crop, 460,000 tons; 1923-24 crop, 550,000 tons; 1924-25 crop, 590,000 tons.

It is estimated that to complete the rehabilitation of the French beet sugar industry there will be required an additional expenditure of about \$4,825,000 (with the franc at 19.3c.).

Canada's Coal Trade for 1920

The output of Canadian coal mines in 1920, according to figures compiled by the Dominion Bureau of Statistics, was 16,968,568 short tons, as against 13,919,096 short tons in 1919, being an increase of 21.9 per cent and a record in the history of coal mines in Canada since the previous high mark was set in 1913 at 15,532,878 short tons. Exports increased to 2,558,223 tons, as compared with 2,070,050 tons in 1919, and imports from the United States were 20,815,596 tons, against 16,982,773 tons in 1919.

Except in Saskatchewan, the output of coal in 1920 in the Canadian provinces was everywhere in excess of that mined in the previous year. Alberta led in output, with 41 per cent of the year's total production. Nova Scotia produced 37.86 per cent of the total, British Columbia 18.3 per cent, Saskatchewan 1.9 per cent and New Brunswick 1 per cent.

By kinds of coal the increases in output for Canada amounted to 0.3 per cent for anthracite, 16 per cent for bituminous and 5.6 per cent for lignite.

An analysis of the exports of Canadian coal during the year shows Nova Scotia as the principal coal-exporting province, with shipments out of the province for foreign destinations amounting to 1,245,673 short tons, as against 994,107 tons in 1919. British Columbia comes a close second with 1,191,103 short tons in 1920 and 1,014,201 tons in 1919.

Ontario leads in the amount of coal imported, central Ontario receiving 2,945,082 short tons of anthracite last year and 2,978,472 tons the year before. More bituminous coal was brought into Ontario in 1920 than in the previous year, the quantities for the two years being 10,374,324 short tons in 1920 and 7,700,935 tons in 1919.

Importations of bituminous coal from the United States into the Province of Quebec fell off very markedly during 1920, as compared with 1919, the total figures being 2,073,813 short tons in 1920 and 3,503,410 tons in 1919. As regards anthracite, the totals for the two years were 1,544,456 tons in 1920 and 1,378,460 tons in 1919.

Bituminous-coal imports into the whole of Canada amounted to 15,902,632 tons in 1920, compared with 12,010,490 tons in 1919. Anthracite imports were slightly lower at 4,912,964 tons in 1920 and 4,972,283 tons in 1919.

Gasification of Powdered Coal*

A Consideration of the Velocity With Which Reaction Takes Place Between Producer Gas and Suspended Carbon, Using the Results for Estimating a Proposal for Gasifying Powdered Coal or Oil

By A. E. BOURCOUD

SINCE the first practical application of burning powdered coal many attempts and processes have been put forward in order to use the same fuel for generation of industrial or producer gas. However, at the present moment, so far as the knowledge of the writer is concerned, none of the trials made has given enough satisfaction to justify its adoption. To cite only those receiving more or less public report, Gobbe, in Belgium; De Laval, in Sweden; Junquera, in Spain; Marconnet, in France, and Allis-Chalmers (Hirt producer), in United States, have shown that the resulting gases had approximately the heating value of blast-furnace top-gas, containing a high percentage of CO_2 and partially decomposed hydrocarbons, having a relatively low calorific value when cooled, and keeping a great part of the original powdered coal in suspension as powdered coke.

CLASSIFICATION OF PROCESSES

The methods or processes put forward can be divided into two groups, namely: (a) One-step processes and (b) two-step processes.

The one-step process consists in introducing a current of air into a chamber with the theoretical quantity of powdered coal to form producer gas by incomplete combustion. Thus all the fuel is first subjected to a rapid distillation; the air introduced for the incomplete combustion of the whole fuel is generally more than that necessary for the complete combustion of the contained volatile matter, with the result that these volatiles are the very first to burn. A small amount of the fixed carbon also is consumed, a high temperature is quickly produced, and the remainder of the fixed carbon, remaining as powdered coke, reacts with the products of combustion of the volatile matters, decomposing the CO_2 and H_2O into CO and H_2 respectively.

The two-step process divides the operation into two stages; the first introduces air with the theoretical quantity of powdered coal for perfect combustion, and then introduces by a second injection the theoretical quantity of powdered coal to transform the products of combustion into fuel gases. Practical inconveniences prevent the two-step process from being carried out in its theoretical entirety, as will be seen afterward.

Theoretically the same amount of thermic work has to be done in both processes to treat the same kind of coal and to arrive at the same end. Only slight differences in temperatures will result, these due to the way in which operations are carried out.

In both processes the reactions are the same as those in ordinary gas producers, with the difference that partial distillation of the coal is effected in the cool or top zone of a common gas producer, while in gasifying

powdered coal this distillation takes place in zones of high temperature. Thus dissociation of the hydrocarbons is more complete. Provision evidently must be made for this important difference.

As a first impression, it seems that neither the one-step nor the two-step process is distinctly more advantageous with the exception perhaps that the two-step process, although with the slight complication of a second fuel injection and control, makes possible the employment of different kind of fuels for the first injection and the second. A second injection of anthracite, coke or charcoal may be made, which so far have presented great difficulties in the one-step gasification.

Both processes are so simple as to be considered much more handy, compact and controllable than any of the ordinary producers of standard type.

Considering the great advantage to be gained by treating raw materials with such a considerable surface action, it seems curious enough that no better results have been obtained. This in turn suggests that some theoretical reasons underlying practical requirements probably not accounted for have been standing in the way of commercial success. The very presence of large quantities of carbon suspended in the partly decomposed products of combustion making up the final gas evidently shows that complete reaction between carbon and CO_2 and H_2O has not taken place, either due to faulty conditions of temperature or pressure or a lack in time.

To arrive at a more definite conclusion it is convenient to review the causes modifying the velocity of such reactions.

RATE OF REDUCTION

The rate of reduction of CO_2 by carbon has been dealt with exhaustively by several well-known experimenters since Boudouard; later on, among others, by Clements, Adams and Hisking,¹ and by Rhead and Wheeler.² These experiments not only show the reaction as a function of temperature and concentration, but also confirm the general fact in like actions that the rate of reduction is affected by the facility with which the exhausted gaseous compounds are replaced by fresh ones to continue the work.

The above-mentioned researches passed a current of CO_2 through charcoal at different speeds and temperatures; that is to say, giving the molecules of gas every chance to be removed from the surface of the pieces of carbon. On the other hand, if the particles of carbon are maintained in suspension in the very same medium with which they have to react, there is less chance of removal of the exhausted or connected molecules of gas from the zone of influence of the particles of carbon. The rate of reaction must then diminish in

*Excerpts from a communication to the U. S. Bureau of Mines in 1918 on the Possibilities of Oil and Other Fuels Than Coking Coals for the Manufacture of Steel Direct From Iron Ores.

¹Bureau of Mines Bull. 7, 1911.

²Trans. Chem. Soc., 1912.

some appreciable degree, compared to the case of stationary carbon at the same range of temperature.

The writer is not aware of any special experiments carried out on the above lines. However, some interesting information can be deduced from other experiments upon the behavior of coke-oven gas containing an appreciable quantity of CO_2 and suspended carbon, the latter due to the decomposition of the hydrocarbon gases. Simmersbach³ heated such coke-oven gas for different periods, and published the resulting analysis of the transformed gas, showing an increasing amount of CO until the whole of the original CO_2 was reduced. The range of temperatures used was between 800 and 1,200 deg. C., and the time of reaction between eleven and twenty-two seconds.

Lacking more complete information, these data will serve for a preliminary survey of the reasons for the failure of attempts to gasify pulverized fuel.

With these views, Fig. 1 has been prepared, showing

FIG. 1. RATE OF REDUCTION PER SECOND OF CO_2 TO CO

the percentage of CO_2 reduced by carbon per second and at different temperatures:

Curve 1 shows Rhead and Wheeler's series I and II, using pure CO_2 .

Curve 2 shows the results found by Clements, Adams and Hisking under the same conditions, calculated for a time of contact of one second, from their original curve for five seconds.

Curve 3, according to Rhead and Wheeler, for a mixture of 20 per cent of CO_2 and 80 per cent N_2 .

Curve A is the corresponding calculated value, for a mixture of 45 to 50 per cent N_2 , the average final gas made when gasifying bituminous coal or oil, deduced from the average of curves 1 and 2, and curve 3.

Curve B shows the rate of reduction per second with carbon in suspension, calculated from the experiments of Simmersbach. The greater part of curve B has been determined by extrapolation, and although methods of this kind are many times branded as dangerous, in the case under consideration the similarity of all the reactions makes all the curves of the same class, with the sole difference of their respective parameters.

It now remains to compute from these graphical data a curve which will show the rate at which the gas made when gasifying pulverized fuel may be expected to react with the carbon it carries in suspension. Various fuels may be used either in the one-step or the two-step process, and air for combustion may be either cold or preheated. However, the method of computation is in all cases quite similar, and the following solution is given for a dried bituminous coal, gasified in one step with dry cold air.

³Stahl und Eisen, Feb. 6, 1913.

TABLE I. GASIFICATION OF POWERED COAL IN ONE-STEP

Air at 0 Deg. C.

Zone Temperatures, Deg. C.	Cu.M. of Mixture Reduced in Zone	Cu.M. of Unre- duced Mixture at the End of Zone	Percentage Re- duced in Each Zone (100 %)	Per Cent Rate of Reduction per Second (100 r)	Time in Seconds —		
					Partial, Log (1-r)	Total	Cumulative Reduc- tion, per Cent
1545 to 1500	16	249	6.5	80.0	0.042	0.042	6.5

Composition of Dried Coal Proximate

	Per Cent		Per Cent		Per Cent
C.....	75	Fixed carbon...	56	C.....	19
H.....	5	Vol. matter. ...	34	H.....	5
O.....	10	Ash.....	10	O.....	10
Ash.....	10				

Heat produced = 7,089 calories per gram.

Combustion of carbon in 255.3 kg. coal⁴ to CO

$$75\% \text{ carbon} \times 255.3 \text{ kg.} \times \frac{16}{12} = 255.3 \text{ kg. O}_2 \text{ required}$$

$$10\% \text{ oxygen} \times 255.3 \text{ kg.} = 25.5 \text{ kg. O}_2 \text{ from coal}$$

$$229.8 \text{ kg. O}_2 \text{ supplied from air}$$

$$229.8 \text{ kg. O}_2 \times \frac{1}{1.43} = 160.0 \text{ cu.m. O}_2 \text{ (standard conditions)}$$

$$\text{corresponding to } 610.0 \text{ cu.m. N}_2 \text{ (765 kg.)}$$

$$\text{A total of } 770.0 \text{ cu.m. air (995 kg.)}$$

In other words, 255.3 kg. coal is injected with 770 cu.m. air (standard conditions) in unit time.

Assume that the volatile matter first burns to CO_2 and H_2O , and any excess oxygen converts some fixed carbon to CO_2 .

	Products—	
	CO_2 Cu.M.	H_2O Cu.M.
19% C $\times$ 255.3 kg. $\times$ $\frac{32}{12}$ = 129.7 kg. O_2 to CO_2	90.5	
5% H $\times$ 255.3 kg. $\times$ $\frac{16}{2}$ = 102.1 kg. O_2 to H_2O		142.0
Balance of oxygen = 23.5 kg.		
Will burn 9.0 kg. carbon forming.....	16.5	
Total.....	107.0	142.0

The products of this partial combustion are now as follows:

CO_2	107.0 cu.m.
H_2O	142.0 cu.m.
N_2	610.0 cu.m.
C.....	133.5 kg.
Ash.....	25.5 kg.

The next step is to determine the final temperature of this mixture produced by the combustion of the volatile matter plus 9 kg. of fixed carbon. First the heat of combustion of the volatile matter is figured:

$$\text{Heat liberated by total combustion of 100 g. in calorimeter} = 708,900 \text{ Cal.}$$

$$\text{Heat due to combustion of carbon } 56 \times \frac{97,200}{12} = 453,000$$

$$\text{Balance due to volatile matter} = 255,900$$

$$\text{Heat of combustion of volatile matter} = \frac{255,900}{34} = 7,500 \text{ cal. per kg.}$$

⁴255.3 kg. coal is used in the calculation of the one-step process so that the results may be compared with those for the two-step, calculated for a primary injection of 100 kg. of coal and a subsequent addition of another 155 kg. to transform the product of combustion into combustible gases.

FIG. 2. PROGRESS OF RELATION BETWEEN PRODUCTS OF COMBUSTION AND SUSPENDED CARBON

Then determine the heat liberated by assumed partial combustion of 255.3 kg. coal:

By volatile matter 34% × 255.3 kg. × 7,500 cal./kg. =	Cal. 655,000
By 9 kg. carbon 9 × $\frac{97,200}{12}$ =	73,000
	728,000
Less 5% radiation.	36,000
	692,000

This heat is absorbed by the products of partial combustion, bringing their temperature to t .

In CO ₂	107 cu. m. @ (0.37 <i>t</i> + 0.00022 <i>t</i> ²) =	39.5 <i>t</i> + 0.0235 <i>t</i> ²
In H ₂ O	142 cu. m. @ (0.34 <i>t</i> + 0.00015 <i>t</i> ²) =	48.1 <i>t</i> + 0.0213 <i>t</i> ²
In N ₂	610 cu. m. @ (0.303 <i>t</i> + 0.000027 <i>t</i> ²) =	184.0 <i>t</i> + 0.0164 <i>t</i> ²
Carbon	133.5 kg. @ 0.5 <i>t</i>	
Ash	25.5 kg. @ 0.5 <i>t</i>	
		= 79.5 <i>t</i>

Total.....351.1*t* + 0.0612*t*²

But 351.1*t* + 0.0612*t*² = 692,000
whence $t = 1545^\circ \text{C.}$ (incoming air and coal at 0°C.)

We have therefore 107.0 cu.m. CO₂ and 142.0 cu.m. H₂O (measured at standard conditions) entering the reduction chamber in the producer at a high temperature and with sufficient finely divided carbon to effect their complete reduction. Chemical reaction, absorbing heat, will then occur at a continually decreasing rate determined by curve *B* in Fig. 1. It has been supposed that the rate of reduction of a mixture comprising x parts of CO₂ and y parts of H₂O acts with the same velocity as a volume of CO₂ equal to $x + y$ and that the time of treatment is too short to feel the influence of the reversible reaction $\text{CO}_2 + \text{H}_2 \rightleftharpoons \text{CO} + \text{H}_2\text{O}$ in the presence of carbon. For purposes of computation it is handy to divide the reaction chamber into zones, limited by certain temperatures.

The time in the first zone (assumed to be from 1,545 deg. C. to 1,500 deg. C.) may be calculated by the formula

$$t = \frac{\log(1 - k)}{\log(1 - r)}$$

where r is the decimal fraction giving the amount of mate-

rial reduced per second at the average temperature of the zone (scaled as 0.80 from curve *B*, Fig. 1).

In cooling from 1,545 to 1,500 deg. C. the gas loses a certain amount of heat, all of which (barring radiation) is absorbed in the endothermic reactions

The volume of gas so reduced divided by the total amount which may be reduced equals the factor k . The composition of the gas and its sensible heat at 1,500 deg. C. can be calculated by successive approximations, but a simplifying assumption will be made, thus: Figure the temperature of the gas at the end of the reaction and assume that the volume of gases reduced is proportional to the temperature drop. The figured total time for the reaction will then be greater than that derived by more precise computations—an error on the side of conservatism.

Final products of combustion:

CO	75% × 255.3 kg. × $\frac{28}{12} \times \frac{1}{1.25} =$	356 cu. m.
H ₂	5% × 255.3 kg. × $\frac{1}{0.09} =$	142 cu. m.
N ₂		610 cu. m.
Ash		25.5 kg.
Sensible heat in this mixture at t deg. C.:		
CO	356 (0.303 <i>t</i> + 0.000027 <i>t</i> ²)	} = 336 <i>t</i> + 0.0299 <i>t</i> ²
H ₂	142 (0.303 <i>t</i> + 0.000027 <i>t</i> ²)	
N ₂	610 (0.303 <i>t</i> + 0.000027 <i>t</i> ²)	
Ash	25.5 kg. @ 0.5 <i>t</i>	= 13 <i>t</i>

Total sensible heat = 349*t* + 0.0299*t*²

Heat produced by reaction equals that from original combustion less that absorbed by reduction of CO₂ and H₂O by equations noted above.

Absorbed by CO₂ = 107.0 cu. m. × $\frac{1.98}{44} \times 38,800 = 187,000 \text{ cal.}$

Absorbed by H₂O = 142.0 cu. m. × $\frac{0.81}{18} \times 28,900 = 185,000 \text{ cal.}$

Total absorbed..... 372,000 cal.
Original quantity..... 692,000 cal.

Balance at end point⁵ 320,000 cal.
Equate:

$$349t + 0.0299t^2 = 320,000$$

whence $t = 875 \text{ deg. C.}$, the temperature of the gases at the end.

Reverting to the assumption of proportionality between sensible heat and temperature, Column 2 of Table I can be readily calculated.

The rest of the data contained in the table can be readily calculated in a manner obvious from the definitions noted at the top of each column. The last column is then plotted as curve 1 on Fig. 2, which shows immediately the time of reaction necessary to convert any portion of the CO₂ plus H₂O into CO and H₂. Eleven cases in all were computed and plotted in Fig. 2, as in Table II.

Temperatures of the various zones plotted against the time consumed in reaching that degree are plotted in the curves of Fig. 3.

Complete reduction and an ideal gas cannot be obtained unless the last traces of the first products of combustion react with the last traces of carbon in suspension at a temperature well above equilibrium, in general 1,100 deg. C. or 1,150 deg. C.

With the exception of coke or anthracite, the curves show therefore that ordinary coals and oil cannot be completely converted into an ideal gas without the addition of external help in the form of preheated primary air. Its temperature varies from the semi-bituminous coals up to oils, the latter requiring a very high tem-

⁵An amount less than that liberated by the CO existing, by the heat absorbed in decomposing volatile matter and heat radiated.

TABLE II. PRINCIPAL DATA FOR FIGS. 2 AND 3

Curve No.	Operation	Fuel	Temperature of Air, Deg. C.	Temperature at Beginning of Reduction	Temperature on 100 per Cent Reduction
1	One-step	Carbon in suspension	0	1,545	875

11	One-step	Oil	1,000	1,712	1,280

perature for gasification into permanent gases. These high temperatures are necessary not only to keep the reactions well above equilibrium, but still more in order to operate in zones where the reactions can take place within a reasonable and practicable time.

To diminish the time taken by the reaction of a given portion of the gas [i.e., for a constant value of $\log(1 - k)$] it is necessary to increase the value of $\log(1 - r)$ as much as possible. That is the same as saying increase the value of r , which in turn is a function of the increase in temperature. The best way therefore to speed up the process is to translate the whole system to a higher temperature zone by increasing the temperature of the primary air.

This influence in the partial and total time taken is clearly evident when comparing the curves 1, 2 and 3

FIG. 3. FALL OF TEMPERATURE DURING REDUCTION OF CO_2 AND H_2O INTO CO AND H_2

for powdered coal with primary air at 0 deg. C., 400 deg. C. and 560 deg. C. respectively and the curves 9, 10 and 11 with primary air at 0 deg. C., 800 deg. C. and 1,000 deg. C. respectively when gasifying oil.

Curves 4, 5 and 6, which have been calculated, are not shown in Fig. 3, as they follow curves 1, 2 and 3 so closely that they can be considered as the same.

The curves 7 and 8 have been calculated with values of r from curve A in Fig. 1 only to show the difference when working with stationary carbon, as in our ordinary gas producer, with gas mixtures containing 45 to 50 per cent N_2 .

Gas from coke gas producers, working along the same lines as a blast furnace, has 80 per cent N_2 at the beginning of CO_2 reduction. It acts still more rapidly, being governed by curve 3 in Fig. 1, which has higher value of r at each temperature than curve A, for ordinary gas producers.

The theoretical temperature of the products of combustion (with the coal used in the other examples), at the beginning of the second stage in the two-step process is about 1,900 deg. C. with air at 0 deg. C., and 2,065 deg. C. with air at 400 deg. C. This would require an excess of coal mixed with the first injection in order not to transgress the practical limits of available refractory materials. A two-step process with excess coal thus reverts to a one-step operation.

REASON FOR FORMER FAILURES

In those examples representing the best results a temperature of 1,700 to 1,800 deg. C. has been reached in the combustion chamber, which is the maximum admissible for the best refractory material to withstand

in daily routine. Even in that extreme case the total time taken for generating a nearly ideal gas for a reducing agent or combustible is between five and six seconds, in addition to the time taken by the first combustion of the fuel in the combustion chamber (about one second), meaning a total of six to seven seconds.

It seems that previous trials in gasifying oil or pulverized fuel have paid too little attention to the time necessary for the reaction and the temperature which must be maintained for its completion. In published drawings and descriptions the path of the gases through the producer is clearly too short to hold them the required time. The resulting gas, moreover, is that which would be delivered by a perfect producer if it were tapped too near the combustion chamber. When utilizing cold air and powdered coal, it is evidently hopeless (from a consideration of Fig. 2) to produce a gas 50 per cent better than ordinary blast-furnace top-gas within a total period of five seconds. ($\text{CO}_2 + \text{H}_2\text{O} = 6$ per cent by volume. $\text{CO} + \text{H}_2 = 35$ per cent.)

PROPOSED PRODUCER FOR POWDERED FUEL

A producer of considerable capacity being desired, let us fix upon one which should gasify about 150 tons of coal (or 600 bbl. of oil) in twenty-four hours.

Two different types of producers are immediately suggested: First, with horizontal combustion chamber, which should have special advantages in the two-step method where different kind of fuels are used for each injection. Second, a producer with vertical combustion chamber, working preferably with the one-step method of gasifying, and in general outlines similar to blast-furnace hot-blast stoves. Only the latter will be discussed in detail.

Fig. 4 shows in schematic lines the general arrangement. Injection of powdered coal and preheated air occurs at I' ; A is the combustion chamber; the path

FIG. 4. SKETCH OF VERTICAL PRODUCER

of the gas follows the dotted line. At the bottom of chamber C most of the ashes can be withdrawn, part of them possibly at the bottom of A, especially if a coal with very fusible ash is utilized. The central passage G has much smaller area than A and C, with the object of accelerating the velocity of the gases, so that the matter in suspension—carbon and ashes—may be better carried up to the top of chamber C. During the whole passage the suspended coal and the gases will have every chance for mutual displacement. Going down, the material in suspension will travel quicker than the sur-

rounding gases; in the up direction, slower. The gases pass finally through *E*, most likely with a small amount of ashes still in suspension. If desired they can be completely cleaned by passing them through a coke scrubber, or any other dry-cleaning system.

It is obvious that in practical operations it would be necessary to use a small amount of fuel in excess of the theoretical and also to provide the bottom of chamber *A* with a well-designed siphon for slagging off the melted ashes.

* Quotient of oxidizing gases by oxidizing plus reducing.

Table III contains the results of a number of simple computations, taking data from curve 3 of Figs. 2 and 3, corresponding to the gasification of bituminous coal by the one-step process, using primary air preheated to 560 deg. C. All volumes have been reduced to 0 deg. C. and 760 mm.

The maximum velocity of the gases during the highest temperature zone at *A* has been limited to 6 m. per second (or about 20 ft.) when expanded at the correct temperature. For facility of construction, the section should be kept constant in area all the way through, with the exception of uptake *G*, where the velocity has been increased to 18 m. per second (60 ft.). The temperature of the gases at the entrance of *G* should be about 1,300 deg. C. maximum, and at this temperature there is no danger of eroding the refractory lining.

Dimensions of Producer

Combustion chamber:

150 tons coal per 24 hr., each making 27,500 cu.m. gas at 1,800 deg. C., produces 47.7 cu.m. per second.
At a maximum gas velocity of 6 m. per sec., this requires *A* to have a cross-section of 8 sq.m.
Its length, assuming 1½ seconds for combustion, is 9 m.
From Table III lengths of zones 1, 2, 3 and 4 total 20.55 m.
Total length 29.55 m. (95 ft.)
Disregarding volume of passage *G*, the volume of reacting chamber = 29.55 × 8 = 236.4 cu.m., or 38 cu.m. per ton of coal gasified per hour.

The required structure with thick heat-insulating walls could doubtless be contained in a steel shell 20 ft. in diameter by 60 ft. high and a 300-ton-per-day producer would have to be 25 ft. in diameter and 70 ft. in height.

General Factors in Belgian Metallurgy, 1920

Out of the fifty-four blast furnaces existing in Belgium in 1913 only ten were in operation on Jan. 1, 1920. On Jan. 1, 1921, among the fifty-two blast furnaces now in existence, twenty-seven were in operation, of which, in twenty-four hours, twenty-three produce 3,748 tons of steel, two produce 277 tons of ordinary pig, and the two others 235 tons of refined pig iron. In 1914 forty-nine blast furnaces were operating, of which forty-four produced 6,615 tons of steel, four produced 280 tons of ordinary pig, and one furnace 85 tons of refined pig iron per twenty-four hours.

In Belgian metallurgy the year 1920 showed, during the first six months, a period of unprecedented prosperity, during which abundant orders at abnormally high prices gave added impetus to reconstruction work, so that by July the general metallurgical production in Belgium had reached 60 per cent of its pre-war record. The month of June saw rails at 1,600 f. a ton, but the price decline of the second half of 1920 and the gradual decrease in demand, together with foreign competition, particularly from German sources, has removed the stimulus for increased production, and while reconstruction work is still vigorously pursued, the production figures for December, 1920, exhibit relatively little variation above those of the preceding July.

It is hoped in Belgian industrial circles that a diminution of production costs by wage readjustments, lowering of coal prices and the restoration of the former preferential freight tariffs for ore transport by rail will have a favorable effect on Belgian offers in foreign markets. The introduction of the 8-hour day, necessitating additional working shifts, has added another important item of wage expenditure. For the purpose of export expansion, large Belgian banking interests with important metallurgical affiliations are recommending a policy of combining for the purpose of specialized production and for the establishment of technical sales organizations in foreign markets. The traditional tendency of Belgian industrial life has, however, been so intensely individualistic and competitive that, despite the necessity of some such innovation, its introduction can result only from the further education of the Belgian producer.

Italian Sumac Production

Sicily is the largest producer of sumac in the world, followed by the United States. The annual output in recent years is estimated at 15,000 tons, a decrease of 50 per cent, compared with pre-war production, due to the lack of cultivation brought about by war conditions. However, it is believed that this is only temporary.

Sumac is of two kinds—male and female. The male species, which is found in the Provinces of Palermo and Girgenti, contains 28 per cent or more of tannin, and is therefore the better of the two. The female leaf averages about 24 per cent tannin and is generally found in the Provinces of Catania and Girgenti. Both species thrive throughout the island at any elevation up to 2,000 feet.

At present there is a slump in the sumac market, owing to the prevalent opinion that prices in the foreign markets will fall. Stocks are now available in Palermo at the following prices: Ground ventilated, 28 per cent, 73.60 lire; leaf, 28 per cent, 71.05 lire; and leaf, 30 per cent, 76.15 lire. The prices quoted are f.o.b. Palermo, per hundredweight Yocum's test.

Recovery of Sugar From Beet Molasses

Description of the Steffens and Strontia Processes Using Alkaline Earth Saccharate Precipitate Methods of Recovering Sugar From Non-Edible Beet Molasses—Specification of Materials—Status of Processes

BY WALLACE MONTGOMERY

THE solubility of sugar is affected very much by the presence of foreign organic and inorganic substances. These impurities limit its recovery from the sirups in sugar manufacture called molasses, from which no more sucrose can be recovered by ordinary methods of concentrating and crystallizing. Therefore some different procedure must be resorted to if the remainder of the sugar is to be recovered.

Ordinarily the sugar in molasses from a beet sugar house amounts to 16 to 19 per cent of the total sugar content in the original beets, and the molasses from 6.5 to 7.5 per cent on the beet weight, though this is increased from 1 to 1.5 per cent by the wash water used in washing the raw sugar, giving us a product of approximately the following analysis:

Brix, deg.....	85-89
Sucrose, per cent.....	48-51
Apparent purity.....	56-60
Ash, per cent.....	10-13
Non-sugars, per cent.....	25-30
Organic non-sugars, per cent.....	18-20

COMMERCIAL RECOVERY PROCESSES

Numerous investigators have studied the problem of the recovery of sugar from molasses and there have been six or eight processes tried with varying success. Of these three only proved to have any commercial value, the osmose, the strontia and the Steffens precipitation processes, the last named being the one almost entirely used at present.

Recent inventions in settlers, thickeners and mechanical filters have done more for the Steffens process in reducing cost and increasing production than anything heretofore. The main essentials for Steffens house operation are good high-grade lime and an abundance of cold water, the water either from natural sources or cooled by refrigeration.

Limestone occurs abundantly in nature and is found in practically all stone formations, but only occasionally in the high state of purity that is necessary for the precipitation process. Only a high-grade stone containing a very low silica and magnesium content may be used. The following analysis is typical:

	Per Cent
Moisture.....	0.01
Silica.....	0.68
Iron and aluminum oxides.....	0.55
Calcium carbonate.....	98.47
Magnesium carbonate.....	0.09
Calcium sulphate.....	0.20
	100.00
Through 200 mesh.....	98.00

INSOLUBLE SACCHARATE PRODUCED

From practice and long experience it has been found that a solution of molasses and water containing 6.2 to 6.6 per cent sucrose is the most economical solution

in regard to lime consumption to handle in the Steffens process. The molasses is mixed with fresh water to contain this amount of sugar, then 15 to 20 per cent milk of lime to sugar solution is added. The milk of lime neutralizes any acids present in the molasses and forms calcium monosaccharate, the first saccharate formed in the process. Theoretically this takes place upon the addition of 17 per cent lime; in practice more is required. However, the addition of 20 per cent milk of lime will give the desired result. The use of milk of lime at this point is a saving in more than one way, because the overburned lime from the kiln is sent to the slaker and used, whereas the lime added as powder must be quick or caustic lime. The dicalcium and tricalcium saccharates are not formed unless the lime is unslaked.

After the addition of the milk of lime the solution is pumped to a cold room, where it is cooled by refrigeration. The temperature is lowered to 9 to 12 deg. C., at which temperature it is pumped to the coolers. The coolers consist of cylindrical vessels with tubes, exactly the same as a standard type evaporator. In the well of this vessel is a stirring arrangement to facilitate the circulation and thorough mixing of the lime.

The lime from the kiln, having been properly burned, is ground in mills, of which the Raymond is the most commonly used type. The powdered lime is blown by fans to storage bins above scales, thence fed to coolers.

Theoretically 54 parts of lime to 100 of sugar will form the tricalcium saccharate, but practically 90 to 125 per cent is added, depending upon the quality of lime, the fineness and the method of adding. The temperature in the coolers is held at about 16 to 18 deg. C., which has been found to give best results, by circulating brine in the calandria of the coolers. The temperature rise due to slaking is considerable and constant attention is required to prevent the temperature from passing 28 deg. C., at which decomposition of the saccharate already formed begins to take place.

FILTRATION

The filtration of the finished cooler solution and recovery of the saccharate is accomplished by means of continuous types of filters, of which the Oliver is used quite extensively. These filters consist of a cylindrical drum partly submerged in the finished cooler solution. The filters have a valve arrangement that allows vacuum to be applied to the lower half of the drum, thereby causing the saccharate cake to adhere to the cloth and the liquor to pass through. Upon revolving further water is applied, displacing the mother liquor and raising the purity of the cake. This washing and recovery of the saccharate are possible because tricalcium saccharate is very slightly soluble in cold water, about 1 part to 100 parts of water.

Any dicalcium saccharate present is washed away under ordinary conditions, as it is soluble in 33 parts of water. The mother liquor and wash water contain the bulk of the impurities originally present in the molasses, also some sugar, which was either dissolved by washing or had not combined with the lime to the formation of the tricalcium saccharate in the first place.

Upon heating this liquor the tricalcium saccharate is formed again, though the composition of the saccharate is slightly different from that formed in the cold.

FIG. 1. LIMEKILN WITH CO₂ RECOVERY SYSTEM

Best results have been obtained by heating gradually in a series of tanks, carrying the final temperature to about 85 to 89 deg. C. As the volume of this solution is considerable, a thickener is made use of here, usually of the Dorr tray type, which removes approximately 70 per cent of the liquor, leaving the denser solution to be filtered again. The second filtration is accomplished in filters of exactly the same construction as the cold filter, only smaller in size. The proportion of hot cake to cold cake is about 1 to 7.

Wash water to the extent of 1 to 1½ lb. to 1 lb. of cake is necessary to replace the mother liquor, which is now practically exhausted of sucrose. The final waste to sewer contains only about 0.20 to 0.35 per cent sucrose, and is very high in impurities.

A valuable byproduct is recoverable from the waste water, though the cost of production is excessive at present. Potash of 32.5 per cent K₂O has been successfully recovered and put upon the market in the form of a char for use as fertilizer.

USE OF CALCIUM SACCHARATES

The mixed cold and hot precipitate or cakes are mixed with wash water from the presses in the factory proper or with thin juice, the purified juice of the beet ready for evaporation. This is mixed to a density of 30 to 32 deg. Brix and is used to defecate the raw

juice from the beets, being added in the carbonation tanks. In non-Steffens houses milk of lime is used for this purpose.

Upon the addition of carbon dioxide taken from the limekiln to the juice and the mixture of saccharate the latter breaks up, the lime combining with the CO₂, forming CaCO₃, and the sugar goes into solution with the juice present.

By good Steffens operation it is possible to recover from 92 to 95 per cent of the sugar originally present in the molasses. By reference to the chart or flow sheet a mental picture of the process is more clearly obtained. The quantities and analyses are only approximate, but are good examples of actual working condition in modern factories.

STATUS OF PROCESS

The photographs give some idea of the equipment necessary for the recovery of the sugar from the molasses. The Steffens process has never been applied successfully to the working of molasses from cane sugar products, due to the excessive amount of invert sugar present, though several processes have at times attracted attention, one in particular, that of Batelle, in which the glucose is destroyed at an early stage of the process and the resulting liquor worked the same as raw juice from beets. Nothing has ever been done on a large commercial scale as yet in this direction.

There is still unlimited room for improvement in the Steffens process, although it has reached a state of

FIG. 2. STEFFENS HOUSE FLOW SHEET

high efficiency in the last few years. One of the problems is reduction of lime consumption. Why do we have to add from two to three times the theoretical amount necessary? Another phase of the industry is the recovery of the valuable salts present in the waste

FIG. 3. FILTER, COOLER, LIME HOPPER AND SCALES

by some cheap recovery process. The sugar chemist and engineer have an open field in these lines, and no doubt new methods or equipment will be developed.

STRONTIA PROCESS

Recovery of sugar from molasses by the strontia process is based upon the fact that sugar will combine with the basic oxide of strontium, forming saccharates, rather more insoluble in water than the calcium salts. Of the alkaline earth combinations barium saccharate is the most insoluble, and is the most readily precipitated and filtered of the three, but its commercial application is hindered, due to the fact that an electric furnace is required to convert barium carbonate to barium oxide and because some of the salts which may remain in solution are poisonous. The Steffens process is much more simple than processes using barium or strontium, although the recovery of sugar is not as high nor the purities of the saccharates so obtained as good.

The strontia process was first applied commercially by Schiebler, though a French patent was issued to Dubrunfant and Leplay as early as 1849. Two methods have been developed, based

upon the use of strontium oxide, the mono- and di-saccharate. The method first tried, the monosaccharate, was based upon the equation:

The monosaccharate is only slightly soluble in water and about 60 per cent of the sugar can be recovered. The remaining sugar is precipitated as disaccharate:

The advantages of the method were less strontia used than in the disaccharate process and a greater concentration of the waste water. Owing to the fact that a reversible action would at times set in, as may be seen by the equation, the process was abandoned for the disaccharate process:

In the disaccharate method advantage is taken of the fact that the solubility of strontium disaccharate in

boiling solution is very low; upon cooling crystallized strontium hydroxide separates, leaving sugar in solution. The reactions are:

upon cooling,

Commercially the process is carried on as follows: An excess of strontium hydrate is added to the molasses solution, and the solution heated to boiling, precipitating the disaccharate, which is separated by filtration and washed. The filtrate is cooled to a low temperature and strontium hydrate crystallizes from the solution. The crystals are separated from the mother liquor by a centrifugal and returned to process. The disaccharate is suspended in water, a sugar solution, or in some instances separately, and is allowed to cool gradually, when the strontium hydrate crystallizes, leaving the sugar in solution. The strontium hydrate is separated by a centrifugal and the crystals are returned to process.

The remaining liquor, which is saturated with strontium hydrate, is carbonated, precipitating strontium carbonate according to the equation:

Strontium carbonate is recovered by filtration and reduced to the oxide in a specially designed furnace. The filtrate containing the sugar in solution passes to the evaporators of the sugar factory.

The strontium oxide from the furnace is dissolved in water, forming strontium hydroxide, and is used over again. The waste waters obtained from the solution after precipitation and removal of the disaccharate are cooled to allow the excess of strontium hydrate to crystallize out. These crystals are returned to the process and the mother liquors carbonated and filtered to recover the remaining strontium as strontium carbon-

QUANTITIES USED IN STRONTIA PROCESS

ate and the filtrate is concentrated to recover the potash and nitrogen contained.

The accompanying diagram will give an idea of the quantities used in general practice. These vary, of course, due to differences in equipment, in the grade of strontia used, and in the skill of the operators.

OPERATING DATA

A few figures of interest in the operation follow:

	Per Cent
SrO on sugar in molasses.....	105-112
Equivalent SrCO ₃ (SrO × factor 1.42).....	149-159
Loss in waste water.....	4- 7
Approximate recovery in strontia house.....	93- 96
Approximate recovery in main factory.....	92- 95
Loss of SrCO ₃	3.5- 5
Approximate moisture of SrCO ₃	55- 60

FIG. 4. STRONTIA PROCESS FLOW SHEET

If we were to follow one ton of molasses of 50 per cent sugar content through the entire strontia process we would have figures about as follows:

First Cycle

2,000 lb. molasses
1,000 lb. sugar
930 lb. sugar recovered in saccharate cake
865 lb. sugar recovered as granulated sugar
15 lb. sugar lost in press cake

Second Cycle

50 lb. sugar enter strontia house
47 lb. sugar recovered in saccharate cake
44 lb. sugar recovered as granulated sugar
1 lb. sugar lost in press cake

Third Cycle

2.0 lb. sugar enter strontia house
1.8 lb. sugar recovered in saccharate cake
1.5 lb. sugar recovered as granulated sugar
0.3 lb. sugar lost in press cake

Summarizing we have:

1,000 lb. sugar in molasses:

	Lb.
Granulated sugar obtained.....	910.5
Sugar lost in press cake.....	16.0
Sugar lost in waste waters.....	73.5

For the working up of one ton of molasses we would require:

	Lb.
Theoretical strontium oxide.....	1,136
Theoretical equivalent to strontia carbonate.....	1,631
Actual equivalent to strontia carbonate.....	1,925
Loss of strontia carbonate, 5 per cent on theoretical amount.....	81
Requiring an additional make-up of.....	96.25

REBURNING A DIFFICULTY

Approximately 40 per cent of the strontium oxide used in the process is recovered as the carbonate. This has to be calcined. The calcining of strontium carbonate is best carried on in a rotary kiln and a temperature of 1,175 to 1,250 deg. C. is required. The kiln should be driven by a variable speed motor at from 35 to 60 revolutions per hour. The fuel consumption will vary with the condition of the strontia carbonate, but ordinarily 55 to 65 gal. of oil per ton of calcined strontia will be sufficient, this giving approximately a 90 to 92 per cent conversion. Using gas as fuel, 8,500 to 9,500 cu.ft. of gas per ton will be sufficient.

The general application of the strontia process is hindered by the high cost of the rock and the cost of reburning to oxide. In the Steffens process the limestone used is so much cheaper that the recovery of the calcium carbonate and the reburning to the oxide is not necessary, although the reburning of calcium carbonate

is carried on at one large beet sugar factory here in the United States. The working up of the waste waters of the strontia process requires about 15 to 20 per cent less evaporation than does the waste from the Steffens process.

There is a large field for investigation in either process and no doubt we shall soon hear of improvements in both methods of extracting sugar from waste molasses.

Union Sugar Co.,
Betteravia, Cal.

[EDITOR'S NOTE: In the article by Mr. Montgomery in the March 16 issue of this journal, entitled "Refinery Practice in Beet Sugar Manufacture," lines 2 and 3, second column, page 469, should have read: "The quantity of cake varies with the process, but usually amounts to from 400 to 480 lb. per ton of beets sliced." The figures were inadvertently printed "40 to 48 lb."]

Guadeloupe's Vanilla Crop

The 1920-21 vanilla crop of Guadeloupe began to be picked and bought by buyers about Jan. 15, 1921, its movement before that time having been prohibited by the various municipalities to prevent its being picked too green, and also on account of the fact that the early crop offered for sale before that date is usually stolen vanilla.

Local buyers began by paying about 4.25 f. per kilo for green vanilla. This was increased gradually to a point where a few sales were made at 7 f., but the last rates quoted are 5 to 5.50 f.

When cured the vanilla will be sold for the most part in the United States at the prices then prevailing in New York, and there is therefore usually a large element of speculation in its purchase, due to the fluctuations in the New York market and to exchange.

It is estimated that the present crop of green vanilla is about 200,000 kilos, which when cured will amount to about 85,000 lb., more or less, according to the degree of shrinkage. This will be over twice as much as last year's cured product, which amounted to about 38,000 lb.

Manufacture of Dextrine in Japan

The manufacture of dextrine in Japan is a comparatively new industry, having been organized on a commercial scale only during the past three or four years. It is principally used in the textile industry. Japanese dextrine is exported chiefly to Great Britain, small quantities going to the United States, amounting in 1919 to 132,160 lb., valued at \$11,945. Vice-Consul Dickover notes that at present the manufacturers are not making a profit and unless living costs and wages are reduced, bringing a reduction in the cost of materials and manufacturing, it is possible that the industry will not survive the depression. The cost of production per 100 lb. is approximately \$5.53, while the price of dextrine in the markets of Osaka and Kobe is around \$5.13 per 100 lb. for white and \$5.58 for the yellow. There are three small dextrine factories in Japan, one in Osaka, one in Tokyo and one in Kyushu, and the total output for all Japan is about 300 tons per month.

Belgian Coal Production

Belgian coal mines during December produced 107 per cent of average monthly production during 1913. Coke and briquet yield in December equaled the March record of 123 per cent of 1913 average. Total coal production in Belgium for 1920 was 22,433,535 tons.

Coefficients of Equivalence in Ternary Alloys*

General Discussion of the Effect of Adding a Little of a Third Element to a Binary Alloy—Mathematical Development of Equations Defining Isomicrographic Lines, and Boundaries of Zones Showing Two Well-Defined Constituents

BY LÉON GUILLET AND ALBERT PORTEVIN

SYSTEMATIC studies on special brasses made by one of the authors¹ have shown that when an element is added to a binary alloy the following cases may occur:

(a) The added element retains its identity (Pb in brass).

(b) The added element forms an isolated special constituent—that is to say, a chemical compound or a solid solution (P and Mg in brass).

(c) The added element enters in solution in one or both of the normal constituents of the binary alloy.

The first case is of little industrial importance; in the second case the free constituent lowers the elongation and the electrical resistance of the alloy; the third case is very frequently met with in steels, brasses and bronzes and is of great industrial importance. It will be considered here in detail.

THE THIRD ELEMENT FORMS SOLID SOLUTIONS

When the added element enters into solid solution a double effect results which can be clearly explained in binary alloys having transformations and a eutectoid,

FIG. 1

and whose equilibrium diagram is as illustrated in Fig. 1. The incorporated element can then displace the eutectoid point *E* either vertically or horizontally, or both.

By vertical displacement extremely interesting results are obtained. Thus let us suppose that the transformation point corresponding to the formation of a eutectoid is at a sufficiently elevated temperature so that its structure may be well developed. It may then be easily studied with the microscope. A temperature in question

is the well-known $Ar_{1,2,3}$ in the iron:carbon system, 700 deg. C. (1,290 deg. F.). An alloying element can lower this temperature so that even with slow cooling Ac may lie between 350 deg. C. (660 deg. F.) and room temperature. It is known that under these conditions the metal is martensitic, or self-hardening. The transformation point may be lowered even to below atmospheric temperature, in which case the alloy presents an austenitic structure and consists of a solid solution which is stable at room temperature as well as high temperatures.

If the transformation point remains around 500 deg. C. (930 deg. F.) the lamellar or granular structure usual to eutectoids is replaced by the so-called osmondite, characterized by a uniform dark coloration when etched by a slightly acid reagent. These facts are illustrated by nickel steels and manganese steels. Martensitic structures have also been noted by Robin² in tin bronzes containing arsenic, and in aluminum bronzes containing both tin and zinc. (See also the work of Andrew and Edwards³ on the alloys Cu:Al:Sn.)

If a binary alloy possesses a eutectoid point which, at a normal cooling rate, occurs at a relatively low temperature, the alloy could present osmonditic, martensitic or austenitic structures, depending upon the quenching velocity. On the other hand, the presence of a third element might raise the transformation point and consequently produce very marked and variable effects, depending upon circumstances.

No martensitic or austenitic binary alloys are known—at least with certainty—although this ought to be the case for Fe:Ni and Fe:Mn alloys. It is probable that the presence of such an element as aluminum or silicon, which raises the transformation points, induces the decomposition of austenite and at times brings out the eutectoid structure characterized by pearlite.

STRUCTURE OF β BRASS

Some copper:zinc alloys naturally give an osmonditic structure. Due to the low temperature of the eutectoid point (470 deg. C.), the alloys with 53 to 63 per cent copper contain the then unstable constituent β , which has the aspect of a solid solution, the two eutectoid constituents into which it disintegrates cannot be distinguished. Carpenter has tried his best to agglomerate the particles of this eutectoid into microscopic dimensions, but without success, even after heating for four months at the boiling point of sulphur (445 deg. C. or 833 deg. F.). After "priming" the decomposition of β by fourteen days' contact at 445 deg. C. (833 deg. F.) with a brass containing 0.95 per cent vanadium and then continuing the heating for ten days at the same

temperature, he was able to render the components α and γ visible under the microscope.

One of the authors⁴ has resolved the eutectoid into the α and γ constituents by very slow cooling, taking seventy-five hours, from the liquid state to 300 deg. C. (570 deg. F.). By assuming that the respective sizes of the pro-eutectoid (α solid solution) and eutectoid constituents are modified in the same proportions as the cooling rate is varied, he was led to assign sizes of 0.1 to 0.01 μ to the constituents of the eutectoid after a normal rate of cooling—i.e., of the same magnitude as that of colloid particles.

In studying the influence of a third element on osmonditic structure in brass, Carpenter has found that the addition of bismuth, lead or manganese does not have any appreciable influence, whereas the addition of silicon, aluminum, iron and especially nickel and vanadium develops a characteristic eutectoid structure clearly. Guillet,⁵ working on nickel brasses, has found similar results, but he has also noticed the very important fact that whenever lamellar structure appears under the microscope, thermal analysis of the sample reveals an elevated transformation temperature.

THE EUTECTOID IS MOVED HORIZONTALLY

A change of the position of the eutectoid point in a horizontal direction due to the addition of a third element to a binary alloy corresponds to the creation of a fictitious composition when determined by the microscope and equilibrium diagram and which is different from that given by chemical analysis. One of the authors⁶ has made a detailed study of such changes in the position of the eutectoid point. It has been found that the presence of manganese and chromium in steel results in a modification of the relative proportions of pearlite and ferrite, and this causes a fictitious carbon content to result from computation based on planimetric survey.

It is to be noted that this is also the case for certain special steels, especially for eutectoid tungsten and molybdenum steels. In these the carbon content decreases with an increase of the tungsten or molybdenum contents. In brasses the eutectoid is not resolved, and the resulting structure appears the same as though ordinary room temperature were 500 deg. C. (932 deg. F.). In brasses the $\alpha + \beta$ zone permits determination of the fictitious composition with the microscope because in this zone the copper content is rigorously proportional to the amount of α constituent contained.

MATHEMATICAL EXPRESSION

The general study of the phenomenon can be expressed by the formula⁷

$$A' = \frac{100A}{100 + q(t - 1)} \quad (1)$$

which gives the relation between the real percentage of element A as determined by chemical analysis, the fictitious composition A' as determined by microscopic examination, the quantity q of the third element and its coefficient of equivalence t .

As before, t is defined indirectly thus: A third element added to a binary alloy A:B possesses a coefficient

of equivalence t when 1 per cent of this body will enter solid solution and replace t per cent of element B, the proportion thus obtained being figured to 100.

Let us consider the extreme case of a binary alloy formed of metal A and quantity q of C, the third element, as for example when passing from the ternary brass Cu:Zn:Al to the binary alloy Cu:Al.

We have then

$$A + q = 100; \text{ or } q = 100 - A$$

and by replacing this value of q in the general formula just above

$$A' = \frac{100A}{100 + (100 - A)(t - 1)} = \frac{100A}{100t - A(t - 1)}$$

and

$$A = \frac{100tA'}{100 + A'(t - 1)} \quad (2)$$

It is known⁷ that t for aluminum = 6.0, and that in ordinary brasses the zone $\alpha + \beta$ is limited by 63 and 53 per cent copper. What will these limits be in Cu:Al alloys?

$$\text{For } A' = 63 \quad A = \frac{100 \times 6 \times 63}{100 + 63 \times 5} = 91.1$$

$$\text{For } A' = 53 \quad A = \frac{100 \times 6 \times 53}{100 + 53 \times 5} = 87.1$$

The Cu:Al diagram indicates 92.5 and 87 as limits for the $\alpha + \beta$ zone. This shows how near the calculated data approach the real.

GENERAL REPRESENTATION

Let us now consider the case from the general point of view and utilize Fig. 2, the triangular diagram representing the composition of ternary alloys. To fix

FIG. 2.

our thoughts, confine the discussion to brasses, and let the points Z, C and M correspond respectively to pure zinc, copper and the third metal M. By taking the point Z as origin, a point m situated in the interior of the equilateral triangle will represent an alloy of the composition: A per cent copper ($A = Za$), q per cent M ($q = Zb$) and B per cent zinc ($B = 100 - A - q = mc$).

Between 63 and 53 per cent copper the binary brasses are formed of two constituents α and β ; there exists therefore in the interior of the triangle a zone where these two constituents may be found and whose limits cut side ZC at the two points noted.

For a point m situated in the interior of this zone the alloy is formed of the two constituents in the ratio

$K = \frac{\alpha}{\beta}$. The locus of points m for which value K is constant is called an isomicrographic line, and cuts ZC at n , the fictitious composition of the brass. The micrography of these alloys will be defined by the ratio K , or by the fictitious content in copper (A').

Points such as m are fixed in relation to A , A' , t and q by equation 1 above. Assuming that within limits the value of t remains a constant for a certain metal, the co-ordinates of m (A and q) fulfill the equation

$$\frac{A}{A'} - \frac{t-1}{100} \times q = 1$$

derived from equation 1. Or more simply

$$\frac{A}{A'} + \lambda q = 1 \quad (3)$$

$$\text{where } \lambda = \frac{1-t}{100}.$$

Within the limits of constancy of A' and t equation 3 of the isomicrographic line, being of the first degree, plots as a straight line, and the intercepts on the ZC and ZM axes are A' and $\frac{1}{\lambda}$ or $\frac{100}{1-t}$ respectively. As A' varies, equation 3 represents a pencil of lines con-

verging on $q_0 = \frac{100}{1-t}$, as has already been indicated

by Cavalier.⁸ Further all the isomicrographic lines for a given element (t constant) pass through a point

defined by the co-ordinates $A = 0$ and $q_0 = \frac{1}{\lambda}$ —i.e.,

a point situated on the line ZM at a distance from Z equal to $\frac{1}{\lambda}$ (point p , Fig. 2). The outermost isomicro-

graphic lines converging from this point limit the zone $\alpha + \beta$, for instance, and separate it from the α and β areas. If λ is positive, the addition of the metal M to an ordinary brass of two constituents will lower

the proportion $\frac{\alpha}{\beta}$ between its constituents and *vice versa*.

With $\lambda = 0$, the isomicrographic lines are all parallel to ZM , and the substitution of the metal M for zinc therefore will not change the appearance of the alloy. That is to say, metal M is equivalent to zinc, or $t = 1$.

The notion of the coefficient of equivalence implies therefore two hypotheses: That t is a constant as long as the third element remains the same, and that A' is constant for various values of q . An identical mathematical expression results when one proceeds in the opposite direction—i.e., by assuming that the isomicrographic lines in the $\alpha + \beta$ zone are straight lines and that these lines converge to a point situated on the ZM axis. This double hypothesis is contained in the definition of the coefficient of equivalence which states that the coefficient has, for a given metal M , a numerical value which is independent of q and A' .

The intercept q_0 is positive or negative, according to whether t is smaller or greater than unity. There are therefore two categories of metals: One giving a fictitious composition greater than the real—i.e., increasing the ratio $\frac{\alpha}{\beta}$ (such as Ni, Co, Mn, Fe in brass), and the other lowering this ratio (Al, Si, Sn).

For $t > 1$, $q_0 < 0$. Point p is below the line ZC (Fig.

3). The isomicrographic lines n, m , and the limits of a certain structural area form an angle smaller than 60 deg. with ZC , and the prolongations of these lines intersect side MC of the equilibrium triangle.

For $t = 1$, $q_0 = \infty$. The isomicrographic lines n, m are parallel to axis ZM .

For $0 < t < 1$, $q_0 > 100$. Point p is beyond M on the

FIG. 3

line ZM and the isomicrographic lines n, m , will intersect side MC of the triangle.

For $t > 1$, $0 < q_0 < 100$. Point p is located between M and Z (isomicrographic lines n, m).

It is not advisable to extrapolate the results of these formulas, as the numerical values of the coefficients t have been obtained for relatively small values of q . Therefore it is unsafe to prolong these lines until they intersect the sides of the triangle. But when the ternary diagram as Cu:Zn:M contains a zone, such as $\alpha + \beta$, joining the two sides CZ and CM of the triangle (as is the case of the system Cu:Zn:Al), a satisfactory representation of the isomicrographic lines can be obtained by prolonging the lines across the triangle (Fig. 4).

The co-ordinates of the point of intersection of the isomicrographic lines with the side CM of the triangle are obtained by solving simultaneously equation 3

and $\frac{A}{100} + \frac{q}{100} = 1$, the equation of the CM axis.

This done, the abscissa or copper content is found to be $A_0 = \frac{t}{\frac{1}{A'} - \frac{1-t}{100}}$. Inspection shows this ex-

pression to be identical with equation 2.

FIG. 4

The coefficient of equivalence of zinc when substituted for aluminum in a Cu:Al system can be obtained by similar reasoning.

If t_1 is the coefficient of equivalence of the metal M to Zn in the Cu:Zn system and t_2 the coefficient of equivalence of Zn to the metal M in the Cu:M system, the isomicrographic lines converge in a point

p on the side ZM . We have $\overline{Zp} + \overline{pM} = \overline{ZM}$.

But $\overline{Zp} = q_0 = \frac{100}{1-t_1}$. Hence by symmetry we get $t_1 t_2 = 1$, or $t_2 = \frac{1}{t_1}$. Thus, since the coefficient of

equivalence of the aluminum when substituted for Zn

⁸Cavalier, Leçons sur les alliages métalliques, Paris, Vuibert et Nony, 1909, p. 301.

in Cu:Zn brasses is 6, the coefficient of equivalence of zinc in aluminum bronzes for the $\alpha + \beta$ zone is equal to $\frac{1}{6}$.

These extrapolations seem to be possible only in the system Cu:Zn:Al, because in other ternary brasses the $\alpha + \beta$ zone does not extend across to the CM axis, its limit being a zone $\alpha + \beta + \gamma$, γ denoting a third phase constituted by a definite compound, by a solid solution, by a eutectic or a double or triple eutectoid.

It is to be noted that the coefficient of equivalence does not indicate the general attitude of a metal toward a pair of metals. The conception only applies to a zone of two well-determined constituents. Thus the coefficient of equivalence of Sn in Cu:Al alloys is approximately 0.3 to 0.4 for the $\alpha + \gamma$ area and equal to 1 for the $\gamma + \epsilon$ zone.

A specific property is not indicated by the coefficient of equivalence, but it is a sure and sufficiently precise guide to outline the modifications in the constitution of low ternary alloys and consequently in their properties.
